The dabbing brush stems slide in guides in brackets K on the framing (one of which is shown at fig. 1); pivoted to this stem is a rod L hung on a crank pin projecting from a pulley M. A band from a pulley N on the shaft F drives this pulley M, and thus a rapid up-and-down motion is given to the dabbing brush. This mode of driving greatly diminishes the wear and tear of the brush, which owing to the teeth of the combs (in their continuous rotation) dragging through the depressed brush have hitherto been rapidly deteriorated. At fig. 1 is shown an arrangement for feeding the combs, which is to be provided in duplicate so as to feed at opposite sides the comb A.

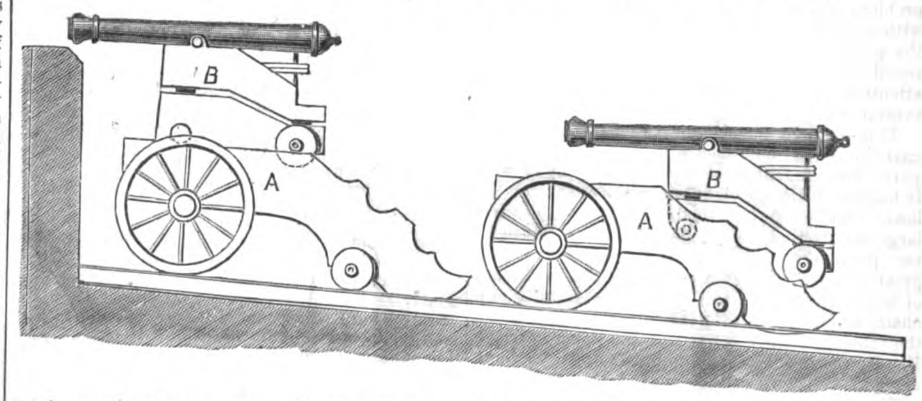
The operation of the machine is as follows:— The wool or other fibre to be combed as it is laid on the combs (at points coinciding with the line of their centres) is pressed down into the teeth by the dabbing brushes, and a continuous rotary motion being imparted to the combs in the direction of the arrows the adjacent teeth of the combs A and D laden with fibre will gradually recede, each set of teeth retaining a portion of the fibre supplied thereto. Those fibres which are carried round by the large comb A will be taken up by the drawing-off rollers O and delivered to a pair of condensing rollers P which serve to condense into one roping all the combed fibres taken up by the several sets of drawing-off rollers. In like manner the fibres carried round by the combs D are removed from the comb teeth by their respective drawing-off rollers I and led to the condensing rollers P. Before, however, this stripping of the combs D commences the inverted combs G will in their rotation have come down over and in front of the comb teeth carrying the fibres, and thus the fibres when seized by the rollers I will be drawn through the combs G, the teeth of which will intercept the noils and the burrs or other extraneous matters contained in the fibres, and thus ensure the delivery of cleaned fibres to the rollers.

NOBLE LIFEBOAT SERVICES DURING THE RECENT GALES.

The following is a list of the great services rendered to shipwrecked crews by the lifeboats of the National Institution during the heavy gales of the past and present months:—French lugger "Isabelle," of Dinan, four men saved by the Padstow lifeboat; screw steamer "Hellenis," of Dublin, officers and crew, consisting of twenty-one persons, rescued by the Arklow lifeboat; schooner "Prudence," of Watchet, crew of three men saved by the Burnham lifeboat; schooner "Lady Anne," of West Hartlepool, crew of five men and vessel assisted by the Margate lifeboat; ship "Electric Spark," of Boston, U.S., twenty-one of the crew and the master's wife saved by the Wexford large lifeboat; yacht "Emetic," of Dunmore East, three men and vessel saved by the Dungarvan lifeboat; barque "Empress," of Prince Edward's Island, eighteen persons saved by the New Brighton tubular lifeboat; Dutch schooner, crew of three men and vessel assisted by the Burnham lifeboat; steamer "Viking," of Dundee, seven of crew rescued by the Fraserburg lifeboat; smack "Active," of Selsey, vessel saved by the Worthing lifeboat; the crew of two men of a small sloop rescued by the Castletown lifeboat; brig 'Phillis and Mary," of Blyth, vessel and crew of eight men assisted by the Cadgwith lifeboat; boat of the "Brave Chilion" saved by the Worthing lifeboat; smack "John James," of Chester, two men and vessel saved by the Aberdovey lifeboat; billyboy "Swan," of Hull, six persons rescued by the Sutton lifeboat; schooner "Gipsy King," of Glasgow, one man saved by the Moelfre lifeboat; schooner "Elephant," of Ulverstone, one man rescued by the New Brighton tubular lifeboat; brig "John and Mary," of Shields, nine men saved by the Blakeney lifeboat; brig "Ravensworth," of Hartlepool, six men saved by the same lifeboat; ship "Frank Shaw," of Shields, thirteen men rescued by the Broadstairs lifeboat, and one man by the Ramsgate lifeboat; brigantine "Gleaner," of Carnarvon, three men rescued by the Porthdinllaen lifeboat; schooner "Trusty," of Boston, crew of three men saved by the Sheringham lifeboat; steam whaler "Diana," of Hull, thirty-one men saved by the Donna Nook lifeboat; schooner "Commodore," of Waterford, crew of five men and vessel rescued by the Ilfracombe lifeboat; and sloop "Ann Elizabeth," of Barnstaple, crew of four men and vessel saved by the same boat.

This long list makes a total of 181 lives rescued by the lifeboats of the Institution during the late storms, in addition to 9 vessels saved from destruction. In the same period the crews of the lifeboats of the following stations either assembled or put off 31 times in reply to signals of distress from vessels not ultimately requiring their services:—Appledore, Southwold, Courtmacsherry, Wicklow, Courtown, Lowestoft, Pakefield, Rhyl, Lizard, Eastbourne, St. Justinian, Ilfracombe, Cahore, Withernsea, Ramsgate, North Deal, Hasborough, Peterhead, Sutton, Saltburn, Skegness, North Berwick, Newbiggin, Cromer, Broughty Ferry, Donna Nook, and Hunstanton. It often happened that on these occasions the lifeboat crews had incurred much risk and exposure throughout stormy days and nights. It should be remembered that nearly every life that has been saved by lifeboats during the recent storms was rescued under dangerous circumstances; and it will be thus seen what great benefit has been conferred by the Lifeboat Institution, not only on the poor men themselves and on their country, but also on their wives and children, who would otherwise be widows and orphans. During the storms of the present year the Institution has contributed, by lifeboats and shoreboats, to the saving of 781 lives from various wrecks. The Society has now 210 lifeboats under its management; and it is gratifying to know that nearly every large place, like Liverpool, Ramsgate, Scarborough, Dublin Bay, Montrose, and other important stations, is now supplied with lifeboats. It is therefore only at small fishing villages that lifeboats are now mostly needed, where, on account of the poverty of the localities, the whole expense, amounting altogether to £650, of the first establishment of the station has to be provided by the Institution, in addition to an outlay of £50 a year to keep up the station in a state of permanent efficiency.

THE MONCRIEFF SYSTEM ANTICIPATED.



THE ROGERS LOCOMOTIVE AND MACHINE WORKS.

THE first locomotive, the "Sundusky," was turned out at these works, at Paterson, New Jersey, in June, 1837 (then under the firm of Rogers, Ketchum, and Grosvenor), after sixteen months of labour. In this engine were first introduced several improvements, among which we may mention the cone in the smoke-pipe, which was curled over at its base, the cone being perforated with small holes in order to distribute the force of the blast equally over the surface of the wire bonnet. The driving wheels, which were of cast iron with wrought-iron tyres, were cast with hollow spokes, rim and hub, excepting the spokes opposite to the crank, which were cast solid in order to counterbalance the cranks. The engine was also provided with double eccentrics and hooks on the outside of the frame, and altogether was a very neat and tastefully finished locomotive. Mr. Rogers was the first to use expansion braces; he was also among the first, if not the first, to build 10-wheel engines; and also to appreciate and adopt the link motion at a time when it was pronounced by many to be a humbug. It has always been a special feature in the Rogers engines to give ample boiler, with large steam room, and they have always been noted for their durability and economy of fuel.

In 1856, at the death of Mr. Rogers, these works had turned out about 800 engines, when the works passed into the hands of an incorporated company under its present name, and W. S. Hudson, Esq., was chosen superintendent, and under whose management the works continue at the present time. The works have been enlarged, and other extensive additions are still in progress to keep pace with the demand for engines. Mr. Hudson has introduced many valuable improvements in locomotives, among which we may mention the application of cross equalising levers to four and six wheel engines, so as to make them equivalent in action to a "three-legged stool" or tripod; also a system of equalising levers between driving and truck wheels, which has been successfully applied to engines with six drivers and one pair of truck wheels, also to engines with four driving wheels, and a single radiating truck at each end, for which Mr. Hudson has procured a patent. Several of these engines have been built, and are in successful operation. We wish to call special attention to this engine, as filling all the requirements of an engine which will run equally well either end first. We will quote what Mr. Hudson says about it:—

"The locomotive is on eight wheels, four driving and four truck wheels. The truck wheels are arranged in two radiating trucks, one at each end of the locomotive; each truck is connected by a combination of levers with each pair of driving wheels. The front truck and driving wheels are equivalent in action to a centre-bearing truck, and the rear truck and driving wheels to a side-bearing truck. With this arrangement all the wheels accommodate themselves to the vertical inequalities of the track without changing the distribution of the weight, and without interfering with the radiating of the front and rear truck wheels of the engine. The fixed wheel base may be made very short, so that the engine will pass readily and easily around curves of very small radius without that jumping motion which is inseparable from the ordinary four wheel switching engine, and without danger of getting off the track. The wear of the driving wheel flanges will also be much lessened, and the danger of running off on that account will be very much diminished. For these reasons, the engine is especially adapted to switching, construction, and branch traffic, running, as it does, equally well either end first. The locomotive is very easy on the track, the distribution of the weight and the accommodation to all inequalities of the rail, whether vertical or lateral, being perfect."

Mr. Buckhout, in his report on the New York City Central Underground Railway, recommends the adoption of this style of engine, with some modifications as to condensing the steam, &c., as being better calculated to supply the want for motive power than any of the plans which had been brought to his notice, and in his report, pages 19 and 20, describes the general design, and comments as follows:—"Gauge, 4ft. 8½in. Fuel, anthracite coal or coke. Cylinder, 14in. by 22in., four 56in. driving wheels, steel tyres, all flanged. Two single-axle radiating trucks, one at each end, wheels 30in. diameter. Furnace of steel; 126 2in. flues, 10ft. 5in. long. Tank on each side of engine to contain 1,500 gallons. The engine also to be supplied with a blower or steam jet. The engine to be so arranged as to throw the exhaust steam into the tanks so as to condense it or throw it up the chimney for the purpose of blast for raising steam, and so that the engineer can make the change instantly as required. This engine will take 80 tons in addition to its own weight (68,000lb. in running order), with 1,500 gallons of water in the tank, and 600lb. of coal, up grades of 1 in 39, or 38ft. per mile, with a pressure of steam as low as 80lb. per inch (if the steam should get so low), cutting off at 60 per cent. admission, it being intended to carry a maximum of 130lb. per inch. About 1,400 gallons of water will be required for the condensation of the steam for the distance of two miles, consequently it would require changing every four miles, if the steam were condensed for half that distance. The tanks to have a discharge valve, by which the water can be let out quickly when it requires changing. The fixed wheel base to be 6ft. 9in., and the whole base, including the radiating trucks at each end, to be about 21ft. 9in. With this arrangement the truck wheels will not require to radiate over 3¼in. from a straight line, on curves of 200ft. radius, which is much within the limits of its capability. With equalising levers, as applied to this description of engine by Mr. Hudson, two-thirds or more of the weight can be carried on the drivers, and the arrangement is such as to accommodate itself to all the vertical and lateral undulations of the track without varying the distribution of the weight on the wheels; it is also arranged so as to be equivalent in action to a four wheel centre-bearing truck at one end, and to a four wheel side-bearing truck at the other end. In addition to these properties the engine can be run either end foremost with great facility and equal safety: a feature not embraced in any four driving wheel single truck engine. It has therefore special advantages in saving the time usually occupied in turning an engine round so as to run truck foremost. It has another advantage. The trucks do not deviate from the centre line of engine nearly as much as a four driving and four wheel swing truck engine does on the same curve, being some 50 per cent. in favour of the double truck."

The Rogers Locomotive Works are adding facilities to enable them to turn out 15 to 20 locomotives per month: they are now producing 10 or 12 locomotives per month. They have furnished a large number for the Union and Central Pacific roads, and are still building for those lines. Two of their engines, the "Success, No. 156," and the "Excelsior, No. 157," were built for the Central Pacific, to make the first through trip from the Atlantic to the Pacific shores, and their whistles have already been heard sounding through the Sierra Nevada mountains. These works have also furnished many for South America, to climb over the Andes mountains, over grades of 264ft. per mile. The good working qualities of the Rogers engines are well understood and appreciated by the engineers, with whom they are great favourites; they are tasteful in design, and in finish and ornamentation second to none others. These works are using steel largely in their engines, both for tyres, axles, boilers, slides, crank pins, and for many other parts.—"American Railway Times."

Correspondence.

ENGLISH AND CONTINENTAL INTERCOMMUNICATION.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Permit me to draw your attention to the enclosed list, which I have compiled from the most accurate data, as to the relative rise and progress of ideas by engineers and others for practically connecting England with the European and Asiatic continents, as it no doubt existed in olden times, the entrance or disjointure having been effected from time to time by volcanic or oceanic storms. This will probably prove an interesting rider to Mr. Nursey's paper upon the subject, the first part of which appeared in your last issue.

Permit me also, with reference to that portion of that paper in which my tunnel scheme is described, to remark that the statement conveys the idea that my project arose in 1868. It will, however, be found referred to in the "Mining Journal" for 1856, and also in the "Times" and "La Presse." At that time, I laid my plans before the Civil Engineers' Institute, and was complimented then and there by opinions "that my ideas and plans were very good—but premature by thirteen or fourteen years."—I am, Sir, yours, &c.,

W. AUSTIN, C.E.

8, Culmore-terrace, Carlton-road, Old Kent-road, October 25.

RELATIVE PROGRESS OF DESIGNS FOR CROSSING THE CHANNEL—ENGLAND TO FRANCE.

1. M. Mathieu, 1801, proposed submarine tunnel—no detail or estimate.
2. MM. Franchot and Mottray, in 1803-4, cast-iron tunnel on bed—no detail or estimate.
3. M. de la Haye, Liverpool, 1845—55, iron submerged tunnel—£10,000,000.
4. M. Victor Horeau, 1851, submerged iron tube and double rails—£87,400,000.
5. M. Payerne, 1855, concrete tunnel on sea bed—no estimate.
6. M. Faure, 1855, submarine under-Channel bed—£4,000,000.
7. Mr. James Wytson, 1855, iron floating tube (subaqueous)—£15,000,000.
8. Mr. Nicholl, 1856, iron tube (subaqueous)—no estimate.
9. M. Vacherot, 1855-6, iron and concrete lined tube—no estimate.
10. Mr. W. Austin, C.E., 1856, triple arch oval masonry submarine tunnel, with three double lines of railway, subsequently corrected to circular or ring masonry, &c.—£16,000,000 original *calculus*; £21,000,000 revised estimate.
11. Messrs. Turner, Dublin, 1856, semi-circular submerged iron tunnel, brick cased—no estimate.
12. M. Thomé de Gamond, 1857, tunnel and thirteen islands—£6,800,000.
13. Mr. J. F. Smith, 1861, floating iron tube, submerged and moored—£10,000,000.
14. Mr. Chalmers, 1861, iron drift or tunnel, submerged, lined with concrete—£12,000,000.
15. Mr. Remington, 1863-4, an oval submarine brick-lined tunnel, being almost a fac-simile of one-third of the original oval masonry tunnel of Mr. Austin—£7,000,000.
16. Mr. Hawkshaw, 1864-5, a single arch submarine brick-lined tunnel, with two railways only, and including a subway double drift—£10,000,000.
17. Mr. Bateman, 1869, an iron pneumatic-worked tube of 13ft. clear diameter, with only one pair of railway lines to and from for all traffic—£8,000,000.
18. Mr. C. Marsden, 1869, iron tube or drift on sea bed—£12,260,000.

P.S.—Bridges and ferries being only temporary and non-reliable in event of hurricanes, silting and shifting of harbours, &c., I have not in any way given attention to these.

THE MONCRIEFF SYSTEM ANTICIPATED.

SIR,—Referring to your recent description of Captain Moncrieff's system of mounting heavy guns, permit me to submit to your notice an account of a gun which is intended to answer the same purpose, and which embodies similar principles to those of Captain Moncrieff. It is described and illustrated in a French work published at Milan, in the year 1811, by an anonymous author, General Comte C—. The title is "Essais sur quelques Parties de l'Artillerie et des Fortifications." The first part relates to a description of

a gun carriage for position and siege, to fire without embrasure. The author there states that the problem of finding a gun carriage in order to fire without embrasure, that is to say, which elevates the piece when one wishes to fire, and which the recoil lowers after its discharge, had engaged his attention since 1792, and had also occupied that of several others.

This carriage consists of two parts, the lower carriage A and the upper one B; the upper supports the gun, and is connected to it by a bolt. It has four little wheels between the cheeks of the lower carriage A, two small ones before, and two large ones behind, which are intended to wheel in two parallel grooves. On the axle tree of the great wheels of the lower carriage A is fixed a drum of iron, having fillets to receive the extremity of a chain, which appears similar to that of a watch; the other extremity is fixed to the upper carriage B. By the recoil of the gun, the upper carriage descends as shown in the annexed sketch.

The Republican Italian Government of the year 1805 ordered that this invention should be tried, and it appeared to give some satisfaction after much trouble and alteration. The other trial was by an order of the French Republic in 1803, with a 24-pounder French gun. The results were favourable. The platform had 5deg. elevation, or 1in. to a yard. After the recoil, the distance of the mouth of the piece from the crest of the parapet was 3¾ metres or 12ft. 3in. English. It appears to me that an enfilading battery will destroy Captain Moncrieff's guns, except there are traverses on the parapets. If they are used in the face of a bastion, there must be a traverse at the salient angle. A shell, loaded as described in Marten's patent with molten iron, will, on striking the piece, be likely to cover the carriage and burn the platform, if of wood, and therefore be rendered entirely useless. Molten iron might be used with effect in destroying the gabions, hurdles, fascines, and sandbags of the batteries, parallels, and approaches at a siege.—I am, Sir, yours, &c.,

London, October 25. R. G. Clark.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Received.—C. M. and Co.—W. R.—F. H. L.—T. T. R.—H. S.—M. and C.—E. M.—G. W. H.—C. D. A.—H. C. S.—J. B. W.—R. M.—G. W.—H. B. T.—F. F. G.—W. S.—E. J.—S. E.—G. W. H.—J. E.—J. G. S.—J. F.—C. H. N.—R. B.—J. N.—T. W.—H. J. G.—A. W. T.—F. S.—E. J. L.—B. B.—E. A.—C. E.—D. G.—F. R. S.—W. B. R.

Meetings for the Week.

Mon.—Royal Institute of British Architects.—Ordinary General Meeting. Sir William Tite, M.P., President, will deliver an "Opening Address," at 8 p.m.

Society of Engineers.—Discussion on paper read by Mr. Perry F. Nursey on "English and Continental Intercommunication;" should time permit, a paper will be read by Mr. Charles J. Light on "The Need for further Experiments on the Strength of Materials," at 7.30 p.m.

Thurs.—Special General Meeting, at 6 p.m.

Sat.—London Association of Foremen Engineers.—A paper will be read on "The Warsop Aero-Steam Engine," at 8 p.m.

Naval, Military, and Gunnery Items.

John Kitts, 107 years of age, has presented to the Baltimore city council a claim for services rendered the city in the wars of the Revolution of 1812.

"E.B." has, through Mr. Mark Whitwell, of Bristol' sent a "thank-offering, for mercies received," of £100 to the National Lifeboat Institution. "E. B." may possibly have been saved from a watery grave by one of the lifeboats of the Institution during the storms of the past week.

The West India and Pacific Steamship Company have entered into a contract with the Post Office for a monthly service of mails between Liverpool and Port au Prince, Mexico, Venezuela, and Santa Martha. The basis of the payment is to be 2s. 6d. per ounce for letters, 3d. per lb. for newspapers, and 5d. per lb. for books, patterns, &c.

The "Polynia" has arrived in Dundee with only two fish (26 tuns) from Cumberland Gulf. The other Dundee vessels were at Cape Kater on September 11 without any fish. The season had been bad for fishing on account of the strong winds, which kept the ice north until the fishing time was past. The "Polynia" was alone all season.

According to the last return of the "Bureau Veritas" of Paris, the number of vessels reported to be totally wrecked during the months of August and September last, was 381, of which number 164 were English, 49 French, 23 North German, 22 Norwegian, 19 American, 13 Dutch, 9 Italian, 8 Swedish, 7 Danish, 6 Russian, and 61 sailing under various other flags.

H.M.S. "Devastation," which has recently been laid down at Portsmouth, is to be built with two turrets on the "breastwork monitor system." She will be propelled by double screws with separate engines, and her armament will consist of four 30-ton guns, two on each turret. She will be unlike the "Monarch" or "Captain," inasmuch as she will have no masts or forecastle, although having all round fire.

Three iron steam vessels have just been commenced at the works of Messrs. Maudslay, East Greenwich. A co-operative company, at Millwall, have received orders to build a wooden vessel and a composite vessel. A vessel has just been commenced at Messrs. Rennie's yard. It is stated that Messrs. Dudgeon, at Millwall, have several orders in hand, and there are other indications that an improvement is about to take place with regard to shipbuilding on the Thames.

The annual prize of honour at Brussels was shot for on Tuesday week. It consists of a silver cup of the value of 5,000f., given by the English National Rifle Association, remaining for a year in the possession of the winner, and five guineas, added by Captain Styan, of the Queen's Westminster Rifles. The competitors are limited to the three men in each corps who made the highest scores at the butts of their respective bodies in the Belgian National Guard. The winner was M. André, of the Charleroi Infantry.

The "Cumbrae," screw, lately built and engined by Messrs. W. Simon and Co., Renfrew, has made a satisfactory trial trip, having attained a speed of about 12¼ nautical miles per hour. The "Cumbrae" is the property of the Clyde Shipping Company, and will form one of their South of Ireland steamers. The dimensions of the "Cumbrae" are as follows:—Length, 207ft.; breadth, 27ft.; depth, 15ft.; burden, 620 tons. She is propelled by a pair of direct-acting inverted surface condensing engines of 130-horse power, nominal.

The iron ramrod did not supersede the wooden one until 1742, when it was introduced into the Prussian army by Prince Leopold, of Anhalt-Dessau. The bayonet was preceded by various contrivances, such as an axe attached to the barrel, then a dagger, etc., stuck into the latter. But, as this was an impediment to firing, a ring was added, about 1691, to the bayonet, whereby the blade, instead of covering the muzzle, came to be flush with its rim. This, however, was still inconvenient for loading, so that at length the bayonet was provided with a neck, as it now is. This was about 1705.

Rear-Admiral Arthur Farquhar will hoist his flag on board the "Black Prince" on the 1st of November, have it saluted, and then proceed on leave. As we stated last week, Captain F. A. Hume and Commander C. G. Fane have been selected to serve under Admiral Farquhar, and Lieutenants A. T. Dale, C. Caffin, and A. J. Leith, and the Rev. H. Alexander, from the "Asia," will also be appointed to the "Revenge," which ship will be ready about the 15th of November to go to sea. Lieutenant Rickman will be flag lieutenant to Admiral Farquhar.

A new iron drawbridge is being erected over the canal at the Royal Arsenal by Sir William Armstrong, at a cost of £3,000. Its object is to connect by a nearer route the landing pier and the North Kent line, avoiding the long and unpleasant curve through the practice range, and saving a distance of about a mile. The bridge will be 121ft. in length and the greater part will swing on a pivot by hydraulic power, so as to admit of vessels passing up and down the canal. Men are now engaged screwing in the iron piles, the canal having been drained to facilitate the operations.

At the last quarterly general court of the Governors of the Marine Society, the committee reported that 92 poor and destitute boys had been admitted into the training-ship "Warspite," off Charlton, during the last quarter; 43 had been sent into the Royal Navy, and 45 to the merchant service. A complement of 160 had been kept on board. Seven young men, who had served their apprenticeship with credit, after passing out of the society ship, were rewarded with medals. The attention of the benevolent was earnestly called to the amount of good this society—the parent of all training-ship institutions—is effecting.

The scientific departments at the Royal Arsenal have under investigation the merits of a 37-barrelled rifle, said to be an improvement upon Montigny's mitrailleuse, which has been already adopted to some extent by the French government. This consists of 37 rifle barrels bound together by hoops, the charges for the whole being contained in a movable breech-piece, and the barrels can be discharged singly or together by a turn of the hand. The "machine" has been found to make a good diagram at the targets, almost too good if it is intended to supersede grape shot. The rifling and the bullets are Metford's, and the charge 15 grains.

Some interesting experiments have taken place at Perm, Russia, with a new 20-inch gun, cast in the foundry of that town. The trials made with this gun, under the direction of Major General Pestitch, commandant of the Cronstadt artillery, are described in the official reports as having been very successful, and more satisfactory in their results than had been the case with American guns of the same calibre. The gun was fired 314 times; the projectile weighs 10 cwt., and the charge of powder required for each shot was 130lb. The weight of the gun is about 50 tons, the recoil 7ft., the initial velocity of the projectile 1,120ft. per second, and the percussion force, at a distance of 50ft., about 10,000 tons. The official papers say this is "the most powerful gun in Europe."

A French writer calculated that, at the commencement of 1867, there existed in the world 2,814 lighthouses, or phares, of more or less importance, viz., 1,785 on the coasts of Europe, 674 on those of America, 162 in Asia, 100 in Oceania, and 93 in Africa. As regards Europe, the best lighted coasts are those of Belgium, France following immediately afterwards. Then come, in the order in which their names are given, Holland, England, Spain, Prussia, Italy, Sweden and Norway, Portugal, Denmark, Austria, Turkey, Greece, and finally Russia. Besides Europe, the best lighted coasts are those of the United States, which have one light for every 20 miles, whilst the Brazilian coast has only one light for every 87 miles. Of the 2,814 in existence at the commencement of 1867, about 2,300 had been established since 1830, while the power of the greater part of those existing prior to 1830 has been increased.

The Director-General of the Ordnance and the Committee of Inventions at Woolwich have under trial a bottle cartridge designed by Colonel Boxer. It is intended, if successful, to supersede the ordinary cartridge in use for small-bore breech-loading rifles, which cartridge, being several inches in length, is very liable to injury. The main principle of the invention is to enlarge the chamber of the rifle without interfering with the diameter of the barrel. The cartridge is, therefore, in the shape of a bottle, the apex or neck containing the bullet, while the base consists of the powder, which, being concentrated more than in the elongated cartridge, is theoretically supposed to possess the property of more rapid ignition and consequent increase of force. All the advantages which attach to a "low trajectory" are, therefore, claimed for the invention, which is not so new as is generally supposed, having been introduced some years since in America. We have had by us for the last five years copper-cased bottle-shaped cartridges for the Spencer repeating rifle.

Miscellanea.

The net profit derived from the Prussian state railways for the year will be about 2,364,722 thalers.

Mr. Daniel A. Lange, director and representative in this country of the Suez Canal Company, will leave London on November 1 for the ceremony of the inauguration of the Suez Canal.

We regret to learn that Mr. George Peabody is lying dangerously ill at 80, Eaton-square. He was in a state of unconsciousness from Tuesday afternoon until Wednesday morning. In the afternoon, we are informed, he rallied slightly, but is still in a critical state.

The Tram-Railway Company have completed their organization, and are now taking into consideration applications from different parts of the country where tramways are required and where the best local support seems likely to be given. A few of the most promising will, it is said, after due inquiry, be proceeded with at once.

On Saturday Lord Ravensworth laid the foundation stone of a building to be used as the Mechanics' Institute at Walker, near Newcastle. The building will be of brick, with stone dressings, and will contain a public hall, a reading room, library, smoking room, class-room, ante-rooms, and a room for the local board. The estimated cost of the building is £3,000.

The number of visitors to the South Kensington Museum during the week ending October 23, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,265; Meyrick and other galleries, 1,423; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,917; Meyrick and other galleries, 126; total, 14,731. Average of corresponding week in former years, 9,931. Total from opening of Museum, 8,901,179.

A definite concession has been granted for Roumelian railways, to connect the Bosphorus with the Sclave and European lines, and open direct communication between Thrace and Macedonia and the ports of Salonica, Enos, and Constantinople. The length of the lines will be 2,000 kilometres. Baron Kirsch and the concessionnaires are to form a company with a capital of 50,000,000f., which will undertake to finish the whole network of railway in seven years.

The Duke of Argyle received at the India Office on Wednesday, the 27th inst., a deputation of the Council of the Institution of Civil Engineers, on the subject of a notification lately issued by the Public Works Department of the government of India. The deputation consisted of Mr. Charles Hutton Gregory, President; Mr. Bidder and Mr. Fowler, Past-Presidents; Mr. Cubitt and Mr. Hawksley, Vice-Presidents; Mr. Abernethy, Mr. Bramwell, Mr. Hemans, Mr. Murray, and Mr. Stephenson, Members of Council; Mr. Manby, Honorary Secretary; and Mr. Forrest, the Secretary.

The immense wealth of the Thames goldfields, in the Northern Island of New Zealand, has given a great stimulus to gold prospecting in other districts of that colony. Thus, in Taranaki, Napier, and Wellington prospecting parties are at work, and substantial success is confidently anticipated. Although gold-bearing quartz has not yet been discovered in the province of Canterbury, the existence of extensive reefs on Banks's Peninsula has been clearly proved, and these will be shortly tested. Prospecting parties are out in the southern, western, and northern parts of the province, and a thorough exploration, at any rate, will be the result.

The Americans say that they had Lieutenant Saxby's storm. The night of October 4 will not soon be forgotten. Two residents of Newcastle, New Hampshire, report that they were on the beach at 10 p.m. when the tidal wave, 18ft. high, rolled in. As they saw it coming, they fled, but one fell among the rocks, and clung to them, the wave going over him. It ran 125ft. above high water mark. In three minutes afterwards there was no trace of it. The tide in the Bay of Fundy, and at and near St. John, New Brunswick, rose to a height never before known. Thousands of cattle and sheep were drowned, bridges were swept away, and miles of railroad track destroyed.

On the night of October 17 and the morning o the following day a snow storm of extraordinary violence swept across Stiria and the adjacent districts. A great deal of injury has been done to the gardens and vineyards, as the vintage is not yet finished; indeed, in some places it has hardly commenced. At Laibach the heat of the 17th was intense, and yet on the following morning at 8 o'clock the snow began to fall. In the night a violent thunderstorm had broken over the district. At Gratz it snowed the whole night and forenoon so heavily that the whole ground was completely covered, and the branches of the fruit trees, still in full leaf, were broken by the weight of the snow.

The inhabitants of Ealing have at last succeeded in obtaining sufficient funds for the erection of a public clock and chimes, which has been placed in the tower of one of the most beautiful churches in the place. The work has been most successfully carried out by the well-known makers, Messrs. Gillett and Brand, of Horology Works, Croydon, who were the manufacturers of the great clock at the International Exhibition, and also the celebrated Boston chimes. Amongst the many great improvements introduced in this new clock is a gravity escapement, the invention of Mr. E. B. Denison, Q.C. There are three faces to the clock, which is illuminated at night by means of gas. The size of the clock may be estimated when it is said that the weights weigh about half a ton.

It is said that the proposal to construct special carriages for native females on the East India Railway has been approved of by the Viceroy. The carriages will be reserved for respectable native women, and are to be "first-class," but with lower fares than those of the ordinary first-class vehicles. It has also been recommended that there should be a European female guard and a European female ticket-collector for the passengers by these carriages. Also that the railway company should see that every station is supplied with a sufficient number of palkees and bearers to convey these ladies on their arrival to their final destinations. An extra quarter of an hour may, it is also said, be allowed to the trains to which the carriages may be attached both at the starting and halting stations.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—998, 1011, 1024, 1027, 1042, 1061

Buildings and Building Materials—993, 1003, 1016, 1026, 1037, 1044

Chemistry and Photography—1046, 1059, 1060, 1070, 1071

Cultivation of the Soil, including agricultural implements and machines—1073

Electrical Apparatus—None

Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—1007, 1022, 1030, 1033, 1072

Food and Beverages, including the apparatus for preparing food for men and animals—987, 996, 1008, 1028 1040

Furniture and Apparel, including household utensils time-keepers, jewellery, musical instruments, &c.—983, 989, 990, 991, 992, 1005, 1006, 1010, 1019, 1036, 1047, 1049, 1052, 1056, 1057, 1067

General Machinery—995, 999, 1023, 1041, 1045, 1054

Lighting, Heating, and Ventilating—947, 1002, 1018, 1021, 1029

Metals, including apparatus for their manufacture—1068

Miscellaneous—907, 981, 982, 988, 997, 1000, 1001, 1025, 1032, 1035, 1038, 1048, 1053, 1058, 1064, 1066, 1069

Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—986, 1009, 1012, 1013, 1014, 1015, 1031, 1034, 1050, 1065

Ships and Boats, including their fittings—1003, 1039

Steam Engines—985, 994, 998

Warfare—984, 1017, 1020, 1043, 1055, 1062, 1063

907 J. R. Baillie, Walthamstow. *Coal waggons.* Dated March 25, 1869.

This consists in the adaptation and application to such waggons of doors or flaps working on a shaft or pivot and moved thereon as required by means of a worm toothed quadrant and worm turned by a winch, or by other means. The door or flap has its pivot nearer to one side than the other of the opening in the bottom or side of the waggon, thereby giving more weight on one side of the pivot than on the other, in order that the flap or door may have a tendency to fall open to its full extent when not controlled by the mechanical means employed for the purpose.—Patent completed.

947 C. Weekes, Great George-street, S.W. *Combustion of wood.* Dated March 30, 1869.

This consists, first, in passing a wire or small piece of wood through holes at or about the centres of any convenient number of sticks or pieces of wood of equal or unequal section such as are commonly sold in bundles for firewood, cut into suitable lengths. Second, in turning the ends of such pieces (thus fixed upon the wire or other centre) so as to produce an arrangement similar to that known as a "chevaux-de-frise," in which state the wood is placed in the grate or fire place, where it is intended for combustion. Pieces of coal or other fuel are then to be placed in the spaces round the ends of the wood, and a light applied at the bottom, sides, or front.—Patent abandoned.

981 T. Lippiatt, Orange, New Jersey, U.S. *Engraving and chasing.* Dated March 31, 1869.

The main bed of the machine supports the heads and extends forwards in the form of slides for receiving the main sliding rest or bed plate which carries the parts operating upon the tool. This plate may be moved nearer to or further from the mandrel as required by the article operated upon, and for this purpose a screw is employed. The mandrel carries a face plate. Upon this face plate the article to be engraved is attached, or in place of a face plate a chuck or other holder may be substituted.—Patent completed.

982 J. C. Lee, Ashton, Chester. *Collecting excreta.* Dated April 1, 1869.

The inventor employs boxes, cases, or receptacles, preferably formed of metal, and fitted with lids, doors, or covers so fitted or arranged as that when the receptacles are closed by means of the lids, doors, or covers, the receptacles may be airtight or nearly so. For the purpose of making the joint between each receptacle and its lid or cover airtight, caoutchouc or any other suitable elastic material may be employed, or a channel may be formed in or on the receptacle, which is to be filled or nearly filled with water, or with a deodorising fluid or material, or with any suitable substance or fluid, into which a flanch formed on the lid or cover dips sufficiently to seal the receptacle, that is to say, to prevent wholly or partially the emission of noxious emanations from within the receptacle.—Patent completed.

983 C. Lange, Strand, W.C. *Clock and watch winding.* Dated April 1, 1869.

The wheel which is geared into and worked by the pinion on which the knob at the pendant is fixed, and which the inventor calls the first wheel, is fixed on to one end of an axle, while the other end of this axle is formed square for the purpose of winding by a key fitted thereto. This first wheel gears into a second wheel, and the two are kept in constant connection and gear by means of a piece of steel or other metal fitted under or over them, and on which the centre or stud carrying the second wheel is fixed. This piece of steel has its turning centre in common with the first wheel, and has an arm to be acted upon for the purpose of setting the hands. On the barrel arbor is fitted a third wheel, and the second wheel is kept in gear with it by the pressure of a spring. By turning the knob at the pendant, or a key fitted on the above-named square one way, the watch is wound up; by turning it the reverse way, the piece of steel on which the stud of the second wheel is fixed moves concentrically with the first wheel, and the second wheel is lifted out of gear with the third wheel.—Patent completed.

984 H. Carter and G. H. Edwards, Bow. *Breech-loaders.* Dated April 1, 1869.

In order to adapt the Chassepot rifle for the Boxer or Daw central-fire cartridge, the inventors first alter the bore of the breech and of the barrel, in so far as the reception of the cartridge is concerned. They take an exact model of the original form of breech, in rear of the rifling, that is to say, so much of the bore and cavity of the breech behind it as is necessary to constitute the receptacle or space for the cartridge when the arm is loaded, and from this model they form a corresponding metallic plug or stopper of similar shape and dimensions. This they subject to a red heat, and insert it firmly into the breech and rear of the cavity or shoe, close to the breech, so as to close or plug the same. They then bore or drill through the body or sides of the barrel, two apertures a short distance apart, and at right angles to each other, passing completely through the sides of the barrel and plug, and they then insert two screws (forming screw rivets by hammering), which serve to secure the plug in position.—Patent abandoned.

985 G. Holcroft and W. N. Dack, Manchester. *Steam engines.* Dated April 1, 1869.

This consists, first, in the application of a balance valve with the back plate placed on a plate or facing behind the ordinary slide valve. Second, in connecting the differential stop to the eccentric rod or its equivalent. Third, in making the governor rod in two parts, each with a head acted upon by springs contained in a box. Fourth, in working the valves of certain ordinary steam engines by applying a catch to the slide worked to and fro by the eccentric.—Patent completed.

986 J. Beckett and A. W. Field, Llandudno. *Railway brake.* Dated April 1, 1869.

To apply this invention to (say) an ordinary railway carriage, the hooks on the outer ends of the drawbacks are each constructed to receive and carry an antifriction roller or wheel, which when the apparatus is in the act of being thrown out of gear travels upon a double cam placed between the front and back drawbars of the carriage, and with a notch therein or ratchet tooth formed thereon at a point slightly in front of the frame of the carriage (when drawn out by the power required to move the vehicle), when applied to the drawhook on the front or back of the carriage, as the case may be. Each drawbar is provided with a lateral stud springing at right angles therefrom or with the requisite projections fashioned to joint a link-rod thereto.—Patent abandoned.

987 E. O'Connell, Greenwich. *Infant feeders.* Dated April 1, 1869.

The inventor provides a cap or cover for the neck of the bottle made of porcelain or other suitable material which is not of a corrosive or deleterious nature, and having a central aperture for the elastic or feeding tube to pass through. Near to or surrounding this aperture he makes one or more holes for the admission of atmospheric air to the inside of the bottle, by the aid of which hole or holes the fluid or other nourishment in the bottle is easily obtained by suction.—Patent completed.

988 J. B. Rowcliffe, Manchester. *Wire cloth for paper machines.* Dated April 1, 1869.

This consists in weaving wire cloth of a twilled, fancy, or basket pattern in an ordinary wire loom to which two, three, or more tiggers or healds are applied for raising and lowering the warp in the succession required by the particular pattern to be produced. In weaving twills, the inventor reverses the direction of the twill or diagonal in the warp at intervals as often as may be required to keep the wire cloth even on the rollers of the paper making machine.—Patent completed.

989 C. D. Norton, Old-street-road. *Revolving heels and tips.* Dated April 1, 1869.

The inventor makes a disc of metal having a rabbet on its inside lower edge, the purpose of which is to permit a reefer, made of a circular piece of metal of a correspond-

ing size, to pass the upper orifice of the disc and bear upon the rabbet for the purpose of attaching the disc to its base upon the boot or shoe. Being thus placed, and the keeper having screw holes perforating its surface it is firmly attached to the boot or shoe by means of screws or nails driven through the holes into that part of the heel formed upon the sole of the boot, at the same time permitting the revolving part of the heel to be easily turned by the hand at the pleasure of the wearer.—Patent completed.

990 T. HIGGINS, Warrington Gardens, W. *Hats.* (A communication.) Dated April 1, 1869.

This consists in constructing hats with a clip or holder on their interior to carry a small hat brush. For this purpose the inventor employs a small spring clip of metal secured to a card, which is glued or fastened in the crown of the hat. The jaws of the clip are formed to embrace the brush, and nip against the sides of its back or handle.—Patent abandoned.

991 J. CAPLIN, Pentonville-road. *Umbrellas and parasols.* Dated April 1, 1869.

Instead of affixing the notch to a piece of tubing or runner cylindrical throughout its entire length, with the edge of the notch projecting considerably beyond it, the inventor forms that part of the tubing or runner situate immediately under the notch with a swell, the larger diameter of which is greater than that of the notch.—Patent completed.

992 W. GIBSON, Birmingham. *Cramp keys.* Dated April 1, 1869.

The inventor makes the cramp key or implement of the same general form as that in ordinary use, that is to say, the implement consists essentially of a cramp and screw with the following additions or modifications. Instead of making the thumb bit or thumb plate of the screw of the ordinary form, the inventor makes the thumb bit in the shape of a square hollow key, at right angles to the axis of the screw, the key serving to screw and unscrew such parts as have square heads which will engage in the hollow key.—Patent abandoned.

993 G. H. WILSON and G. E. PULLEN, Commercial-road. *Window sashes.* Dated April 1, 1869.

This apparatus is constructed in order to be placed on either end of top bar of front or lower sash. It consists of two racks, of a box with two bolts, which take into these racks, of a locking spring, of an adjusting spring, of a lever or arm, and of a drop bolt.—Patent abandoned.

994 W. ALLAN, Sunderland. *Marine steam engines.* Dated April 1, 1869.

The inventor places the condenser below the crank shaft, and makes it to form part of the bed plate. The two ends of the bed plate rest on and are secured to beams or girders which run athwartship, whilst the casing of the condenser is carried down between these beams or girders until it rests on the centre keelson. The tubes of the condenser are placed athwartship, so that the condenser doors or covers by which the tubes are got at are at the two sides of the condenser. The end bearings of the crank shaft can either be carried in separate castings, which castings contain the air and circulating pump chambers, and may be bolted or otherwise secured to the sides of the condenser casing, or the whole bed plate may be in one casting.—Patent completed.

995 W. BAYNE and O. E. M'GREGOR, Wolverhampton. *Carpenters' planes.* Dated April 1, 1869.

The inventor makes the face of the head of the plane movable, so that it can be pushed nearer to the back edge of the mouth or withdrawn from it, according to the extent to which it is worn or the nature of the work to be done. A portion of the head of the plane, carrying with it the whole of the head face about half an inch deep, is advanced and withdrawn by means of a screw which enters the remaining portion of the head. The head face is kept true with the tail face by sliding in a dovetailed groove and by a stud in the movable portion of the head which enters a hole to correspond in the fixed portion thereof.—Patent completed.

996 G. H. SMITH, Colchester. *Cooking indicators.* Dated April 2, 1869.

For cooking eggs the inventor constructs a pan with a perforated bottom working on a hinge, so as to open and shut with a clasp, and to the top of the pan he fixes a whistle or other alarum capable of being operated upon by the pressure of steam. This alarum has a piece of wire gauze placed over its mouth to prevent priming or choking.—Patent completed.

997 J. BATH, King William-street, E.C. *Printing and copying machine.* Dated April 2, 1869.

In a suitable framing the inventor arranges the following parts:—At the front part of the framing he arranges a set of keys horizontally, somewhat similar to the keyboard of a musical stringed instrument, say forty-eight keys for example. Each of these keys corresponds to a letter of the alphabet, beginning at the left hand of the keyboard. The first key corresponds to the capital A, the second key to a small a, and so on in regular order of succession throughout the entire number of keys, every other key corresponding to a capital letter, and the other keys to small letters. In connection with the aforesaid keys the inventor employs a series of levers, all radiating from the key board or converging to a centre at any given distance from the key board. Each of the levers is mounted on an independent fulcrum suitably placed, and a spring is adapted to each for keeping them raised when out of use, and to the converging ends of each of the aforesaid levers the inventor affixes large and small letters, or characters or types in accordance with the letters on the keys. The types occupy a very small space when arranged side by side, say about 2in. for the forty-eight letters. In a line with the key board, or thereabout, he adaps a flat table or tray fitted with a pad covering its surface, upon which is to be placed the blank sheet of paper that is to be printed upon, and upon this blank sheet he places and secures in position a sheet of black, blue, or other coloured transfer capable of giving off the colouring matter with which it is prepared upon pressure being exerted upon any part of its surface.—Patent abandoned.

998 H. A. FLETCHER, Whitehaven. *Steam generators.* Dated April 2, 1869.

This consists in attaching round the sides of the firebox or tube a series of conical water pockets or thimbles, closed at their inner converging ends and opening at their outer or expanded ends, through apertures made in the firebox into the water space surrounding the same.—Patent completed.

999 W. MARSTON, Loughborough. *Bolts.* Dated April 2, 1869.

This consists in the first place in forming that end of the bolt which usually slides into a staple or hole, or past a stop or check plate of a circular or inclined shape upon one side thereof, and, second, in forming a circular or inclined shaped stud on a plate, in which a number of holes have been made, through which screws are passed to secure the plate to the sill or shelf.—Patent abandoned.

1000 F. SCHAFER, Golden-square. *Covers and clips for bottles.* Dated April 2, 1869.

A ring and a cup or cone of indiarubber, sponge, or porous material is fitted between rings secured to the top of a vessel or wine cooler. The cup has a series of radial cuts in it. When a bottle is inserted into the vessel it extends the opening in the rubber ring and forces down the flaps of the cone, thus preventing any escape of cooling properties. As the bottle is lifted, the sponge removes the water from the outside, and the flaps pass under the bottle to remove any drops which escape the ring. A ring of sponge is also placed on the outer rings, on which the bottom of the bottle can be drawn. A spring clip is placed over the neck of the bottle to prevent soiling the hands. It is composed of a ring and a series of tongues.—Patent completed.

1001 J. CRUTTENDEN and T. WELLS, Maidstone. *Mechanism for ballot voting.* Dated April 2, 1869.

This relates to certain arrangements and combinations of apparatus for receiving and registering votes by ballot, whereby only the number of balls corresponding to the number of persons to be elected may be employed. The apparatus consists of one set or sets of revolving doors or turnstiles, through which the voter passes into a portable chamber to record his vote, and then passes through another set or sets of revolving doors or turnstiles out of the chamber. These doors are connected by mechanism, either under the flooring or enclosed in suitable casing above, or by both means, so that the opening of one entrance door secures the closing of the exit door, and when the voter has passed into the chamber, the door by which he entered also becomes secured, and prevents his return except by the exit door. This is accomplished by fitting to the axles on which the doors revolve a plate or disc. Each of these plates or discs has studs or projections on it (preferably on the periphery), which come against the end of a swivel plate forked at each end and placed under the floor or cased above or both. As the entrance door is rotated, the forked end prevents its being opened beyond the required distance. At the same time, the stud on the opposite side of the disc pushes the corresponding end of the plate to one side by acting on the other end of the fork, the swivel plate moving on its centre. This movement causes the fork on the other end of the plate to engage and hold fast the disc of the other or exit door.—Patent completed.

1002 W. Y. CRAIG, Harecastle, Stoke-on-Trent, and S. P. BIDDER, jun., Mitcham. *Safety lamps.* Dated April 2, 1869.

This consists in securing the wire gauze or other casing of the lamp by means of a bolt, catch, pawl, or other similar fastening of iron or steel situated inside the lamp and held in its place by means of a spring. This bolt or catch, on the application of a magnet to the outside of the lamp, will be withdrawn by the attractive power of the magnet, so as to allow of the wire gauze or other casing being removed.—Patent completed.

1003 D. OSBORN, Great Berkhampstead. *Building with concrete.* Dated April 2, 1869.

To avoid the necessity of having to wait until the concrete is set before the building can be continued (after a height of wall equal to the depth of a panel has been set up), the inventor so constructs and arranges the fastenings which secure the panels to the uprights that he can set one panel above the other and secure it in position as shown, without first removing the lower panel. Also to prevent the necessity for pulling down from time to time (during the process of building) all the uprights or vertical supports, the inventor makes them of a moderate length, and adds length to length, relying on the attaching of the panels thereto to secure these lengths of uprights in position. The junctions of the panels and the vertical supports are arranged at different levels so as to break joint with one another.—Patent completed.

1004 S. K. HOXSIE, Philadelphia, U.S. *Boat elevators.* Dated April 2, 1869.

This consists in the combination and arrangement of an elevated platform with reservoirs and altitudinally movable tanks, which receive a supply of water therefrom, which causes them to descend. The tanks are connected with the platform by means of chains or wire ropes, which are supported by means of sheaves, which are elevated in order to raise a boat or other vessel. The latter is supported by the platform when at a proper height and angle for discharging its contents into another vessel or receptacles.—Patent completed.

1005 G. H. ELLIS, New Barnet. *Cleaning boots.* Dated April 3, 1869.

The inventor provides a neat base and pedestal or pillar suitable for standing upon a table, and into this pillar he disposes a vertical shaft having a pulley keyed thereon, with a groove which receives a cord or belt of indiarubber. He then places a horizontal shaft in a suitable bearing through the centre of the pillar, with a driving wheel and handle at the end made to act against the pulley and to drive it noiselessly by friction. Upon the other end of this shaft he disposes a brush, slightly concave upon its surface, and having a sponge or other pad fixed thereto, to receive and apply blacking to a boot held against it. This brush and pad are arranged to be easily taken on and off the shaft.—Patent abandoned.

1006 M. WOLFSKY, Pilgrim-street, E.C. *Locks for bags.* Dated April 3, 1869.

The plate is provided with a long slot down the centre, and is attached to the metal frame which is to be fixed to the bag or other receptacle. The plate has a key bolt working in the slot on its under side in connection with a catch bolt against which it works.—Patent completed.

1007 R. ALLAN, Kelvindale. *Paper machinery.* Dated April 3, 1869.

This consists essentially in dispensing with the woollen or felt jacket which is at present employed on the lower couch roll of paper making machinery, thus using the upper couch roll only covered. The rolls or rollers are preferably ground together, so as to ensure a practically perfect contact or complete joint throughout their length.—Patent completed.

1008 D. NICOLL, Caledonian-road. *Safe for food.* Dated April 3, 1869.

In constructing this safe the inventor prefers to line it with prepared bitumenised paper slabs or boards, whereby it is rendered perfectly air, gas, and water-tight. These chambers may also be made with enamelled sheet iron or any other clean and impervious substance. The opening or door is made to close up to an indiarubber washer. The exhauster, which is placed under the safe, is composed of a board having the same dimensions as the bottom of the safe. To the edges of this the inventor nails or attaches a piece of indiarubber or elastic cloth having a depth equal to the height of the preserving chamber or cupboard, and also nailed or otherwise fastened round the edges of the floor of the safe, and in this floor he has an opening communicating with the gas bag or exhauster.—Patent abandoned.

1009 E. WILSON, Peckham. *Velocipedes.* Dated April 3, 1869.

On the main or driving axle of the velocipede the inventor fixes by keys or other fastenings two ratchet wheels, and side by side therewith, but loose on the axle, are two pulleys. Each of these pulleys carries a pawl or catch, which is formed and arranged to take into the teeth of the adjacent ratchet wheel. Over each of the pulleys an endless belt, strap, or band is passed, which also proceeds over a small pulley at the front of the vehicle. To these straps are attached the stirrups in which the feet of the operator are inserted to propel the velocipede.—Patent abandoned.

1010 W. H. DOUGLAS, Stourbridge. *Jet ornaments.* Dated April 3, 1869.

This consists in ornamenting articles made of jet and vulcanite by sinking the surface to be ornamented and securing the gold leaf and enamel (such as lavender and white) thereto as required.—Patent abandoned.

1011 J. HOWDEN, Glasgow. *Preventing escape of heat from boilers, &c.* Dated April 3, 1869.

This consists in applying the plaster of Paris by surrounding the vessel or surface to be protected in some cases wholly or in part by an envelope of sheet iron, lead, wood, or other suitable material, placing the envelope at a distance apart from the surface equal to the thickness required for the non-conducting material. The plaster of Paris is then made up in its liquid state and run or poured into the space between the envelope and surface of the vessel until the space is filled. The plaster of Paris in a few minutes solidifies without the application of heat, and the envelope may either remain permanently or be removed after the space is filled.—Patent completed.

1012 U. SCOTT, North-street, Fitzroy-square. *Railway and other carriages.* Dated April 3, 1869.

First, the improvements consist in a new method of opening and closing the covered heads of carriages and the covered trucks for railways. Second, in making railway doors to slide in slots made in the pulleys of the carriage. Third, in making carriage locks. Fourth, in making lamp sockets for candles for keeping the candle in position.—Patent completed.

1013 W. E. BROAD, Wychdon. *Railway wheels.* Dated April 3, 1869.

This consists in an arrangement of a loose sheath or elongated bearing and axle whereby each wheel is allowed to rotate independently of its fellow.—Patent abandoned.

1014 G. F. GRIFFIN, Great George-street, Westminster. *Permanent way.* Dated April 3, 1869.

When using wooden sleepers the inventor makes them with one or more deep grooves cut longitudinally to receive the rails, and with suitable holes to receive bolts, which he terms Griffin's regulating bolts. In some cases he fastens thin hoop or angle iron upon the face or upper side on either side of the longitudinal groove or grooves and recesses, thin iron supports in the grooves at the joints and in other places.—Patent completed.

1015 D. J. HOARE, Princes-terrace, Bayswater. *Atmospheric railways.* Dated April 3, 1869.

The inventor employs a slot along the top of the tube, as has before been done, and forms the tube with a vertical flange on each side of the slot. In order to close over the slot airtight he employs a continuous length of vulcanised india-rubber, strengthened if desired with canvas or other material, and on the upper surface of the strip of india-rubber he fixes plates of metal in short lengths. A recess or groove is also made along the top of the inner side of each of the vertical flanges at the sides of the slot, which recess is deep enough for the india-rubber band and the metal plate fixed above it to lie in, so that the top of the metal plates may be level with or below the top of the flanges, whilst the band of india-rubber rests at its sides on the bottom of the recess. A thin band of iron or other metal not quite the width of the open part of the slot may run along under or over the india-rubber to take the strain or drag off it. To raise the band to allow air to pass into the tube immediately behind the piston, the inventor passes the band over a pulley, and to again close down the valve in rear of the piston he employs another pulley connected to or carried by the carriage. By this means a free supply of air is admitted directly on to the back of the piston, and the tube in rear of the piston is filled with air. Afterwards the valve is pressed down on to its seat, and so a perfectly airtight joint may be secured.—Patent completed.

1016 S. SHARROCK, Liverpool. *Roofs.* Dated April 3, 1869.

The beams rest upon the columns, and, supporting the roof, serve also as gutters. The covering for the roof is of corrugated iron, and forms an arch. It is fixed to angle irons on the upper flanges of the sides of the beams, which are suitably stiffened. The tie rods pass from the spring of the arch on one side to a corresponding point on the other side. They are attached to angle irons fixed to the sides of the beams, and bars connect the corrugated covering with the tie rods. Two, three, or more of these bars may be employed in connection with each tie rod.—Patent completed.

1017 F. BOYD, Boston, U.S.A. *Breech-loaders.* (A communication.) Dated April 3, 1869.

The patentee claims, first, a breech-piece having lips upon its upper part in combination with clamps attached to the barrels, and projecting backwards over the breech-piece. Second, two clamps, whether attached to the

barrels or breechpiece, in combination with two cam projections, on which they clamp, and with two barrels arranged to turn upon a suitable spindle, the whole arranged so that the barrels can be thrown to either the right or to the left. Third, the plate or washer attached to the spindle in combination with the raised or cam-shaped surfaces of the bearing plate. And, fourth, the barrels with metal plates at their rear ends in combination with the clamps when the latter are inserted and suitably secured in grooves in the former.—Patent completed.

1018 F. W. H. MEDHURST, Chancery-lane. *Lamps.* (A communication.) Dated April 3, 1869.

The inventor encloses the wick in a tube of suitable length, the lower end of which screws into the usual reservoir containing the liquid to be consumed, and into which the lower end of the wick is immersed. The upper end of the wick is flush with the top of the tube, which is enclosed in a second tube capable of sliding thereon. The upper end of this outer tube rises above the wick tube, and at its upper end is placed a plug or nipple of copper or other suitable material, which may be solid, but is preferably made hollow and closed at the top, the plug being filled with cotton.—Patent completed.

1019 J. G. TONGUE, Southampton-buildings, Chancery-lane. *Parasols.* (A communication.) Dated April 3, 1869.

The stick of the parasol or umbrella is of solid steel, and tempered so as to be strong and light. The stopping springs or catches are not set into a groove in the stick, and new arrangements of sliders are employed so formed that the lining of a parasol can be attached thereto without the stopping catches or springs being cramped in their action.—Patent abandoned.

1020 G. A. ERMEN, Eccles. *Breech-loaders and cartridges.* Dated April 5, 1869.

This consists in constructing the cartridge chamber of a box slightly tapered and of larger diameter than the remaining bore of the gun barrel. The difference in their diameters at their point of junction forms an angular shoulder of about 45deg., and against this the front part of the cartridge abuts when inserted therein preparatory to firing. A second improvement relating to the breech mechanism consists of a sliding wedged-shape block inserted in a slot formed by two plates or arms projecting from the rear of the gun barrel, their extremities being connected to the gun stock.—Patent completed.

1021 W. JOHNSON, Swansea. *Compressing combustible substances.* Dated April 5, 1869.

The machinery consists of a double-acting steam cylinder placed horizontally on a firm bed. The piston rod, which projects on both sides, carries at either end a plunger fitting and working accurately in a long bottomless tube, the upper part or cover of which is made moveable, and is so fitted that, by means of a self-adjusting weighted lever, the outer or delivery aperture of the tube can be either reduced or enlarged so as to regulate the resisting power of the tube to the compressing power of the plunger.—Patent completed.

1022 J. WOODS, J. HAMPSON, and I. and G. FISH, Preston. *Looms.* Dated April 5, 1869.

The troughs are bolted to the brackets, which are made to slide on to a rod, and may be set to any distance and position by set pins or screws. This rod is supported in its position by the brackets, which are bolted to springs which have steady pins against which to bear. On the rods, near the centre or in any convenient position, is fixed a fulcrum cranked bracket, set and regulated or altered by a set pin.—Patent completed.

1023 J. U. ASKHAM, Sheffield. *Anvils.* Dated April 5, 1869.

The inventor first prepares a model of the size and shape of the anvil to be produced. He then places it in a box formed of two or more parts, and covers it with composition. He then fills up the box with sand in the ordinary manner. After the model is removed and the sand perfectly dry (this being done in the usual way), he first pours in through a suitable opening the molten steel to form the face or table; then through the same or other convenient aperture (after the steel on the table is sufficiently cool) he pours in a very mild molten steel, which flows over the table and gives the requisite toughness and solidity to the steel "beck." After a proper time has elapsed, the inventor then pours in through another opening formed for the purpose the iron or metal, which also runs upon the steel and forms the lower part or butt of the anvil, and a perfect amalgamation takes place between the iron and steel. The casting being complete, it is then finished in the ordinary manner for castings.—Patent completed.

1024 J. FLETCHER, Heywood. *Firebars for furnaces.* Dated April 5, 1869.

The inventor prefers to use one central raised bar of the form of an ordinary ridging tile of an inverted V shape, perforated on both its sloping sides, either with or without a similar bar at each side of the furnace perforated on the inner sloping side only, or, if preferred, the transverse section of the central perforated firebar may be a semicircle, and that of the side bars a quadrant or arc of 90deg.—Patent completed.

1025 F. COMMASI, Rue du Colysee, Paris. *Motive power from flow of sea.* Dated April 5, 1869.

The apparatus employed for this purpose consists of a combination of reservoirs, culverts or conducting passages, and machinery, the action of which varies according as the tide is ebbing or flowing, and the description of which cannot here be attempted.—Patent completed.

1026 W. G. WHITE, Laurence Pountney-lane, E.C. *Safes.* Dated April 5, 1869.

In constructing the outer shell of a safe or strong room, the inventor forms it of a single piece of iron or steel, rolled or otherwise, made into a continuous hoop or circle or other convenient form of any required thickness and size in a similar manner to that in which the tyres of railway wheels are formed. This piece of iron is then, by means of hydraulic or other pressure, caused to take the required shape, and so form a depository or safe with the top, bottom, and two sides in one piece without any seam or joint, and the back end or part is closed by means of a piece of iron or steel riveted or otherwise attached to the back by means of angle iron or steel, or else to the edges of the body of the safe, which may be turned or flanged over for the purpose.—Patent completed.

1027 W. JONES and T. SHEFFIELD, Manchester. *Steam boilers.* Dated April 5, 1869.

This consists in constructing and arranging within the shell of a boiler a continuous spiral or curvilinear or other formed pipe that will be contained within a space of the boiler covered by the water. One end of this pipe has an opening in the back plate of a furnace, which may be contained within the boiler. The heat of the furnace and products of combustion enter the opening in the back plate formed by one end of the pipe, from whence they pass in a course through such pipe until what remains of the heat thus circulated through the water space of the boiler becomes finally ejected at the opposite extremity.—Patent abandoned.

1028 J. WINTER, jun., Wardour-street, Soho. *Filling and corking bottles.* Dated April 5, 1869.

The bottle or jar holder is formed hollow and steam-tight, with hollow recesses therein, say six, for example, of the same diameter and depth as the bodies of the bottles or jars which they are intended to receive. On the axis of this holder the inventor fixes a steam chamber open at the bottom and permanently closed at its top and sides, its ends being closed by spring doors, which open to allow the necks of the bottles to enter the steam chamber at one end and to pass out at the other end. These doors close immediately after each bottle or jar has entered and passed out of the steam chamber.—Patent abandoned.

1029 C. CAIRNS, New York, U.S.A. *Heating by steam.* Dated April 5, 1869.

This consists in applying a pump, or two or more pumps working one into the other, or separately, and introduced between the generation of the steam and the article to be heated, so that these pumps shall force the steam into a smaller space, and thereby increase the pressure and correspondingly elevate the temperature.—Patent completed.

1030 J. W. DRUMMOND, Schenectady, U.S.A. *Looms.* Dated April 5, 1869.

This relates to the weaving of fabrics by one or more continuously moving shuttles, which travel in one direction in a raceway along one side of the breast beam, having a long vertical mortice or slot down through which the woven fabric passes. Then the shuttle is carried in a semi-circular raceway around the end of that opening and back on the other side and around the semi-circular raceway at the other end, and so on. The fabric is woven double of two separate breadths, or in the form of a flat bag. The two pieces of fabric pass down through the mortice or slot, and the warps are led into the loom horizontally from opposite sides of the breast beam. The warps go through sectional reeds and through treadles arranged to be raised and lowered by slide motion, or by cams so as to weave plain twilled or other fabrics.—Patent abandoned.

1031 J. GREENSLADE, Steeple, Essex. *Traction engines.* Dated April 5, 1869.

These improvements are designed for rendering traction engines, more especially those travelling on common roads, well suited for ascending or descending steep inclines by mounting the boiler together with the engine so that it may be maintained in a horizontal position and thus keep the water always at the same level whatever may be the inclination of the framing, whereby the priming of the engine is prevented as well as injury to the fire box and tubes from excessive heat, such as is the case when the boiler is fixed to the framing in the usual manner.—Patent completed.

1032 J. STERRIKER, Great Driffield. *Expressing oils.* Dated April 5, 1869.

This refers to Letters Patent dated April 1, 1867. The inventor employs pressing plates having grooved surfaces and pressing boxes such as those described in the specification of the above-mentioned patent, and in order to provide for the plates being firmly held rotatively to each other during the pressing operation, and for obviating the tendency to lateral and longitudinal movement, he connects the plates by a special form of metallic hinge made by preference wholly or partly of steel.—Patent completed.

1033 G. T. BOUSFIELD, Brixton. *Manufacture of paper.* (A communication.) Dated April 6, 1869.

To prepare a composite sizing suitable for sizing fine writing paper, the following materials are used in the following proportions, viz.:—Sago flour, 700lb.; glue, 300lb.; nitric acid (commercial), 15lb.; aqua ammonia (commercial), 10lb.; carbolic acid (crystallised), 3oz.—Patent abandoned.

1034 G. T. BOUSFIELD, Brixton. *Shafts of carriages.* (A communication.) Dated April 6, 1869.

Tubes of metal, either rolled, drawn, or cast, are employed in the construction of shafts, poles, perches, and similar parts of carriages, and such shafts and other parts may be curved or made to any shape desired. The interior of the tubular shafts or other such like parts of carriages may be filled in with resin or with other light material, which may be run in a liquid state into the shaft, and which will afterwards solidify by cooling.—Patent abandoned.

1035 F. F. VILLIPIGUE, Northumberland-street, W.C. *Piercing rock.* Dated April 6, 1869.

These perforators or piercing machines are based upon the principle of a constant equilibrium between the motive force and the resistance offered, that is to say, that a self-acting and incessant equilibrium is established between the resisting forces and a regular and constant motive force applied by means of the handle or crank of the machine.—Patent abandoned.

1036 A. HELWIG, Old Kent-road. *Sewing machines.* Dated April 6, 1869.

This consists chiefly in giving to the needle of a single-thread machine a lateral to-and-fro motion transversely to the direction of the sewing, so that the needle descends alternately on the inside and outside of the edge of the hole. Also in the peculiar means employed for effecting this transverse to-and-fro movement of the needle, and in the combination of such means with the mechanism for giving to the needle the ordinary vertical reciprocating motion whereby the thread is carried through the work.—Patent completed.

1037 J. M. JOHNSON, Maida-hill. *Lavatories.* Dated April 6, 1869.

A shelf or slab, holding one or more basins or vessels placed in one or more rows, is mounted in a stand or framework in such a manner that it is supported in a state of rest when the washing, drinking, or other operation for which the apparatus is intended is going on; and it is capable of being tilted or swung in such a manner as to discharge the contents of all the vessels which it carries simultaneously.—Patent abandoned.

1038 E. O'BRIEN, Liverpool. *Beam balance.* Dated April 6, 1869.

This consists of a balance beam with arms of equal length, to one end of which is suspended the usual scale for carrying the ordinary weights, or a rod on which the weights are suspended, and on the other a box scale, divided into two equal parts by a vertical diaphragm. The bottom of each compartment is hopper shaped, having, by preference, three inclined sides and one vertical side, which latter is formed by the side of the diaphragm which divides the scale into two chambers.—Patent abandoned.

1039 R. B. HOOPER and T. and H. R. NICKSON, Liverpool. *Sheathing ships.* Dated April 6 1869.

This consists in fastening a wood sheathing to the sides and bottoms of iron and other ships or vessels, for the purpose of attaching copper, yellow metal, zinc, or other sheathing thereto, in such a manner as to prevent the latter from, by any possibility, coming into contact or connection with the hull of the vessel, or the bolts which fasten the wood sheathing to which it is attached. The invention also relates to a peculiar form of rivet or bolt used for the purpose of attaching the wood sheathing to the hulls of vessels.—Patent completed.

1040 A. V. NEWTON, Chancery-lane. *Baking oven.* (A communication.) Dated April 6, 1869.

The inventor claims the rotating disc or hearth mounted and operated in the peculiar manner described. Also the crown plate, in combination with the firegrates, covers, flues, regulating damper, flue or chimney, and ash boxes, the whole constructed and arranged substantially as set forth in his specification.—Patent completed.

1041 A. K. B. GRANVILLE, Sandford-on-Thames. *Beating engines.* Dated April 6, 1869.

The inventor substitutes a second roller for the stationary plate. This roller revolves whilst at work, and the reduction of the rag or material is effected by the opposing blades of the two rollers. He sets the cutting blades spirally around the roller, by which means the action of the machine is improved.—Patent abandoned.

1042 W. GOODREDS, Tipton. *Puddling furnace doors.* Dated April 7, 1869.

This consists substantially in introducing and preserving a current of water through the furnace door. The inlet of the water is at the top of the door, from whence it is carried round the stopper hole to the outlet. The water may be carried by any convenient means, but by preference gas tubing of a suitable size and kind is employed.—Patent completed.

1043 J. MASON, Birmingham. *Breech-loaders.* Dated April 7, 1869.

The breech block, according to this invention, is caused to work upon a pin and open in a lateral direction. There is affixed to the pin a short lever, which acts upon a prong which is immediately connected with the extractor, and forms part of it.—Patent abandoned.

1044 W. T. RICKARD, Crown-court, Threadneedle-street. *Cements.* Dated April 7, 1869.

Instead of using drying oil or oils, silicate of potash or soda, or other alkaline silicate, is employed, in combination with the usual solid ingredients. The aqueous portion of the silicate combines with these ingredients, which have a chemical affinity for water, and thereby solidifies them.—Patent abandoned.

1045 R. NORFOLK, Beverley. *Casting screw threads.* Dated April 7, 1869.

The inventor prefers to make use of a core box of the shape required to form one half of the screw. The core-box consists of a bed piece in which a loose rim fits. A screw thread corresponding to that to be produced on the casting is cut on a piece of brass or other metal forming the centre of the core-box, and the sand is rammed in the space between the screw-piece and the loose rim. The parts of the core-box are secured together by pins and cotters or other equivalents, and when the core is removed from the core-box it is dried previously to being placed in the moulding box.—Patent completed.

1046 D. S. CHASE, Belfast. *Combustion of gas.* Dated April 7, 1869.

This consists in the use of a thin vertical bar or plate of solid or hollow steel or other metallic substance placed on edge across the upper surface of the burner and at right angles to a line intersecting the perforations of the burner. The vertical bar or plate may be made to rise above the burner in a rectangular, circular, semicircular, tapering, or other form, and it may be perforated.—Patent completed.

1047 E. COLLARD, Southampton-row, W.C. *Dress improvers.* (A communication.) Dated April 7, 1869.

The object is to improve ladies' dresses by a bustle (or dress improver) which can be expanded or made narrower according to the size required by means of steel springs or whalebones fastened at the right and left angles, an opening being left in the centre of the tube in which the springs are moving.—Patent abandoned.

1048 W. E. GEDGE, Wellington-street, Strand, W.C. *Aerospires.* (A communication.) Dated April 7, 1869.

This apparatus is usually composed of two tubes joined at a right angle and communicating with each other by the opening. In the thickness of one of the pipes, which is horizontal, and towards the joint, is a third conduit placed horizontally, shaped like a truncated cone, and the large opening of which is set and riveted to the edge of one end of the horizontal tube. The opposite opening is of about one third the diameter of the other. Another tube fitting to the lower part of the second tube supports the pivot and permits the rest of the apparatus to revolve on its axis as a weathercock, or to stop according to the direction given to it by the crest, that is to say, always presenting to the wind the large opening of the conical tube.—Patent completed.

1049 H. B. BARLOW, Manchester. *Expanding caskets.* (A communication.) Dated April 7, 1869.

To the base plate are attached two side compartments, between which is a drawer opening from both sides and secured by a spring and pin. Above these are four small inner compartments hinged to the partition which supports an upper central compartment to which two other side compartments are hinged. There are also two more side compartments hinged outside the four small inner compartments. The whole is surmounted by a cover which can be closed so as to secure all the compartments by one lock and key or a padlock.—Patent abandoned.

1050 W. R. LAKE, Southampton-buildings. *Permanent way.* (A communication.) Dated April 7, 1869.
The inventor prefers to use a rail whose upper flange or bearing surface is of the ordinary width or nearly so, while its lower flange is considerably smaller than the upper flange, being only of such dimensions as are necessary to give the required strength to the rail, whereas the metal in the flange of an ordinary double-headed rail is much more than is required merely for the purpose of strength.—Patent abandoned.

1051 J. and J. MENZIES, Perth, N.B. *Shuttles.* Dated April 7, 1869.
This relates to side tipped shuttles, and consists in so constructing their ends that they are prevented from splitting. This is effected by forming recesses in that part of the ends of the shuttles wherein the tip and driving pin are fixed. The recesses may be of various forms, and surrounding the shanks or stems of the tips and driving plates by which these are inserted into and retained in the shuttle. Into the recess a loop of wire is placed so as to fill them, thereby strengthening the shuttle against splitting. In pirn shuttles, whether side tipped or centre tipped, the part whereon the skewer or tongue is fixed is also strengthened by inserting a ring or loop of wire into a recess formed in the wood surrounding it.—Patent completed.

1052 J. H. TEALE, Leeds. *Putting on boots.* Dated April 7, 1869.
This consists in constructing an apparatus having a metallic or wooden foundation or bottom of any suitable form or dimensions. On this foundation or bottom two upright standards or brackets of metal are fixed, the hinder one of which has a forked lever attached to it for the purpose of holding the boot or shoe in position for putting on or taking off. From these brackets or standards two or more pegs protrude for the purpose of being inserted into the straps at the back and front of the boot or shoe to hold the boot or shoe in a position for being put on or taken off.—Patent abandoned.

1053 B. M'EVOY, Birmingham. *New game.* Dated April 7, 1869.
This new game is played principally by means of an appliance which consists of a frame upon which two arches are supported, and which is fixed into the turf or ground by means of spikes which are attached thereto.—Patent abandoned.

1054 J. ROBBINS and J. ALLBUT, Tipton. *Pumps.* Dated April 7, 1869.
The inventors use two vertical pump cylinders and solid plungers, working through stuffing boxes at the tops thereof. The lower ends of these pump cylinders are connected with the fore ends of two short horizontal cylinders respectively, the axis of the horizontal cylinders being in the same line. Pistons in the horizontal cylinders are connected to the opposite ends of the same piston rod, so that when the piston in one of the horizontal cylinders is making its advance stroke, the piston in the other horizontal cylinder is making its return stroke. The pistons have no valves, and the suction pipes, having valves opening upwards as usual, are connected to the rear ends of the horizontal cylinders respectively.—Patent completed.

1055 W. POWELL, Birmingham. *Breechloaders.* Dated April 7, 1869.
This relates to that class of breechloaders called drop-down guns. Underneath the lever by which the barrels are fastened and unfastened is a forked slide, consisting of three parallel bars, a middle bar, and two outer bars, the three bars being connected together at their rear ends by a cross bar. The ends of the outer bars of the forked slide are turned outwards at right angles, and engage in slots made in the sides of the strikers. The forked slide works in a recess in the rear of the body of the gun, and the top end of the spring, which acts upon the opening and closing lever, engages in a slot in the middle bar of the said forked slide. When the lever is raised to unfasten the barrel it forces the spring and forked slide back, the latter withdrawing the striker into the body of the gun. On shutting down and fastening the barrels, the forked slide advances by the action of the spring, but does not carry the strikers forward with it owing to the length of the slots in the strikers, in which the ends of the outer bars of the said forked slide engage. Thus, the unfastening of the barrels withdraws the strikers and leaves them in position to be driven forward by the hammers for the discharge of the gun.—Patent completed.

1056 W. H. DOUGLAS, High-street, Stourbridge. *Glove fastener.* Dated April 7, 1869.
In the centre of the under side of a stud or button the inventor makes a screw hole for receiving the eye or fastener, which consists of a screw with a small plate, of a circular or other suitable form at the bottom, provided with a boss or projection in the centre, in which is an undercut hollow or sink forming the eye of the fastener. —Patent abandoned.

1057 W. H. DOUGLAS, High-street, Stourbridge. *Sleeve links.* Dated April 7, 1869.
This consists of the ordinary flat button, on the back of which the inventor fixes a plate, furnished with a sort of double hook somewhat in the form of one end of the double hook is attached to the plate and the other end is free. Instead of the double hook forming part of or being attached to a plate, as above described, it may in some cases be fixed direct to the solitaire itself.—Patent abandoned.

1058 G. ASHCROFT, Alexandria, Egypt. *Hydraulic presses.* Dated April 7, 1869.
The inventor constructs a cylinder, and in that cylinder a piston, made to work along its length water-tight under considerable pressure. Attached to this piston is a rod or plunger, which fits the neck of a second smaller cylinder, so placed on a common axis as that the piston with its rod moves up and down through their respective cylinders freely.—Patent abandoned.

1059 W. H. BALMAIN, St. Helens. *Oxidising agents.* Dated April 7, 1869.
The inventor avails himself of the fact that manganic acid, whether in combination with a base in the form of a manganate, or just set free, will rapidly and readily absorb oxygen, whether alone or as it exists in the air, or as it might be mixed with other gases and produce permanganic acid, or a permanganate which will yield up readily to any substance capable of combining with it a portion of its oxygen, and return to the state of manganate, which again on its part is ready to reabsorb oxygen and reproduce permanganate.—Patent abandoned.

1060 L. MOND, Farnworth. *Utilising waste soda.* Dated April 7, 1869.
This relates to the utilisation of the residue which is obtained from soda and potash wastes after these substances have been oxidised and lixiviated for the separation of sulphur and sulphur compounds as now commonly practised. For this purpose it is proposed to use the residue in the manufacture of soda and potash in the process called balling, by substituting it for a portion of the limestone or other such substance usually employed.—Patent completed.

1061 W. E. NEWTON, Chancery-lane. *Steam generators.* (A communication.) Dated April 7, 1869.
The invention consists, first, in arranging the tubes and their square or parallelogrammic heads so that the fire is restrained from passing directly upwards between the tubes, and a more tortuous or effective action of the heated gaseous products of combustion is secured thereon. The heads of the several tubes are also made to break joint, and spaces are left round the margin or margins of the combined heads to facilitate the scraping or cleaning of the exterior surfaces of the tubes. Second, the invention consists in a combination with the tubes (arranged as described with their heads or ends) of return pipes or bends, not only to connect each tube with the one immediately above and below it at both or opposite ends of the boiler, but arranged to occupy an oblique or diagonal position, whereby increased facility is afforded for contraction and expansion without breakage of the joints. Third the invention consists in a combination with a boiler of a lower drum arranged on the outside of end bearing or support to the boiler, and connected with the lower tier of main tubes for the collection of mud or sediment outside of or beyond the fire chamber, whereby facility is afforded for detaching the drum when necessary either for cleaning or repair.—Patent completed.

1062 W. T. ELEY, Gray's Inn-road. *Cartridge cases.* Dated April 7, 1869.
The inventor forms a fold or ridge in the metal for the metallic coil of a cartridge case at a suitable distance from one of the edges. He then coils the metal with a fold or edge lengthwise of the coil, and afterwards turns the folded part or edge over upon the edge of the overlapping part of the coil.—Patent abandoned.

1063 C. E. H. C. HEALEY, Strand. *Cleaning breech-loaders.* Dated April 7, 1869.
The inventor makes use of a brush or scrubber, or jag, or their equivalent, which brush or its equivalent is moved to and fro within the barrel by means of an endless band, cord, chain, or wire passing over pulleys or rollers, or suitable substitutes at the muzzle and breech of the fire-arm to be cleaned, the band, cord, or chain being secured to the brush or jag.—Patent abandoned.

1064 J. W. WARMAN, Farringdon. *Organ key boards.* Dated April 8, 1869.
This consists in giving the key a bayonet-like form, the finger portion being the higher; the thumper bar thus resting on the body portion just behind the finger portion will rise no higher than the latter, and consequently be clear of the pin rail of the next manual above. The keys of the topmost manual of a set may be of the usual straight form.—Patent abandoned.

1065 J. I. STASSEN, Euston-road. *Velocipedes.* Dated April 8, 1869.
The inventor steers the velocipede by the hind or rear wheel or wheels. The front or driving wheel, the shaft of which carries the ordinary cranks, is supported and free to revolve in bearings formed in the apex of a frame, by preference somewhat of a bell crank shape. The upright rods of this frame embrace the wheel and are united at top by a pin and bolts. Through the pin uniting the frame a vertical rod passes, carrying the steering handle. The lower end of this rod is joined to a yoke, to which rods extending to the forked frame carrying the rear wheel are attached.—Patent abandoned.

1066 A. H. BRANDON, Paris. *Composition for joining leather.* (A communication.) Dated April 8, 1869.
This consists in mixing certain gums or resins, more particularly amber, gum, elemi Venice, turpentine, copal mastic, and lac, in various proportions by aid of the sulphide or bisulphide of carbon or other suitable solvent of gutta percha or caoutchouc.—Patent abandoned.

1067 H. PARSLOW, Glasgow. *Shaping apparel.* Dated April 8, 1869.
This relates to the form and arrangement of models or templates, which are so shaped that on applying them to the cloth or fabric from which the article of apparel is to be made, and by drawing the outline formed by the edges of the model upon the cloth or fabric (the body of the person being beforehand measured), the shape of the various parts is at once obtained, which ensures a perfect fit of the article of apparel when the parts of which it is to be composed are put together.—Patent abandoned.

1068 A. STEWART and J. WOTHERSPOON, Coatbridge, N.B. *Cutting metal tubes.* Dated April 8, 1869.
The improved machinery comprises various parts mounted upon a cast-iron bench or bed frame, and is provided with adjustable holds to fix the article to be operated upon. The cutting tools are disposed radially on a revolving head or chuck, being fed inwards automatically in a gradual and continuous manner as the action proceeds. The toolholders are fitted into radial guides upon the chuck face, and are moved inwards or towards the centre by radial screws, carried by the chuck and having bevel pinions on their outer ends in gear with a bevelled ring or wheel carried loosely on the revolving chuck and made to turn at a slightly slower or quicker rate than the chuck by the driving details shown and hereinafter described, or by any other suitable gearing.—Patent completed.

1069 R. W. MUNRO, Clerkenwell-green. *Whist markers.* Dated April 8, 1869.
The whist marker is a suitable dial on which are printed, engraved, or otherwise indicated any given number of figures or signs according to the requirements of the game for which it is to be used, and the marker is so arranged that only one number or other sign shall be caused to appear through a hole formed in a suitable case at any given time.—Patent abandoned.

1070 J. PATTINSON, Newcastle-on-Tyne. *Utilising ammonia wastes.* Dated April 8, 1869.
The inventor reduces the waste or skimmings to powder, and mixes with it sufficient powdered lime or other suitable alkaline earth to decompose the chloride of zinc, oxychloride of zinc, and chloride of ammonium existing in the "skimmings." As the "skimmings" are of variable composition it is necessary first to ascertain the amount of chlorine contained in that to be brought under treatment in order to determine what proportion of lime or other alkaline earth is required for the decomposition of the chlorides and oxychloride. For every 35 parts of chlorine contained therein about 28 parts of unslaked lime or about 37 parts of slaked lime or an equivalent quantity of other alkaline earth should be provided and mixed with the "skimmings." A suitable charge of this mixture is put into a retort or into a furnace and heat applied thereto so as to decompose the chloride of zinc, oxychloride of zinc, and chloride of ammonium before mentioned.—Patent completed.

1071 D. and G. HALLAS, Leeds. *Regulating and purifying gas.* Dated April 8, 1869.
The inventors use a tap or cock of peculiar construction. On the face of the centre part (within which the cock turns) they place an index, marked at given intervals to denote that when the handle of the cock is severally opposite to them, gas for the various number of lights which they denote is being passed through. The rotating part of the cock itself is made hollow, and pierced at its circumference with holes of varying size, so regulated that each is capable of supplying a given number of lights and no more, and the gas is emitted into the supply pipe. —Patent completed.

1072 J. A. CHAUFOURIER, Paris. *Self-feeding cotton gin.* Dated April 8, 1869.
This improved gin is composed of a framing carrying the principal parts, consisting, first, of two ginning rollers of small diameter, between which the lap of cotton passes deprived of the seeds, which are discharged without being crushed. Second, of two drawing rollers placed immediately behind the ginning rollers, and serving to draw out the lap of cotton after it has been deprived of the seeds. Third, of two cleaning rollers with flexible casings, which are kept in constant contact with the drawing rollers for the purpose of cleaning the same, and at the same time preventing the lap of cotton from coiling round said rollers. Fourth, of an endless web travelling over rollers within a receptacle, and furnished with inclined card teeth, by the aid of which the cotton is fed in a continuous manner to the ginning rollers.—Patent completed.

1073 A. FRYER, Manchester. *Producing sugar.* Dated April 8, 1869.
The inventor constructs a truck, which he prefers to make entirely of metal, and which is usually furnished with only two wheels keyed fast upon their common axle. This axle projects through the wheels on each side, and at each end of it is placed a bracket resting in a bearing upon it, and hanging down nearly to the lowest part of the circumference of the wheel. Each of these brackets terminates on the outer side in a flange or step, which he prolongs in such a manner that by slightly inclining the bracket its edge comes in contact with the ground. When in position he is enabled to draw the wheels of the cart containing the canes or beetroot on to these flanges, where, when the brackets are again brought to a vertical position, they rest, and the carts thus freed from the ground and resting on the trucks are drawn along the tramway. Several of these carts are usually formed into a train, the fore part of the one being supported by the hinder part of the adjoining one.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated October 19, 1869.

3042 J. and J. Kippax, Bolton-le-Moors, Lancashire. Improvements in the method of weaving counterpanes or quilts, applicable in part to the weaving of some other goods or articles.

3043 M. Henry, Fleet-street, City. Improvements in the construction of bridges, and in apparatus for the purpose.

3044 A. Forder, Wolverhampton. Improvements in the seats or saddles of velocipedes and manumotive carriages used either on land or water.

3045 A. Evans, Grimsbury, Northamptonshire. An improved method of joining or connecting pipes and tubes.

3046 W. B. Robins, Richmond-terrace, Shepherd's Bush, Middlesex. Improvements in syringes and other apparatus for throwing water, for watering plants, and similar purposes.

3047 A. Clegg, Finsbury-place, Middlesex. Improvements in sewing machines.

3048 J. H. Johnson, Lincoln's Inn-fields. Improvements in heating, and in apparatus employed therein.

3049 F. R. Window, Baker-street, Portman-square, Middlesex. An improved process for producing photographs in pigments.

Dated October 20, 1869.

3050 J. Hudson, Fleetwood, Lancashire. Improvements in machinery for opening and closing the gates of railway crossings.

3051 D. Jackson and J. Riley, Oldham, Lancashire, and G. R. Ray, Dukinfield, Cheshire. Improvements in machinery for cutting, shaping, and dressing stone.

3052 W. R. Thomson, Glasgow. Improvements in locks, latches, or bolts for fastening the doors of railway carriages, which improvements are also applicable to other purposes.

3053 A. Munro, Arbroath, Forfarshire, and W. B. Adamson, Glasgow. Improvements in cutlery, edge tools, agricultural and other implements.

3054 J. Scharr, Leeds. Improvements in the manufacture of liquid soap.

3055 B. Sulman and R. Willis, City-road, Middlesex. A quadrantal-action-lever stamping and cancelling press.

3056 W. Heywood, St. Paul's-street, Huddersfield, and J. Bottomley, Kirkgate, Huddersfield. Improvements in carriages.

3057 J. F. Crease, Eastney, Southampton. An improved method of attaching Roman, Portland, or other like cements to iron or other substances.

3058 A. Brady, Maryland Point, Stratford, Essex. Improvements in purifying iron or any other metal.

3059 W. Firth, Rose Villa, Viewforth, Edinburgh. Improvements in the wheels of traction carriages for use on common roads and tramways.

3060 J. Howard and E. T. Bousfield, Bedford. Improvements in the construction of steam boilers.

3061 W. E. Newton, Chancery-lane. An improved mode of, or process for, preserving animal or vegetable substances from decay.

3062 H. Percival, Sunderland, Durham. Improvements in glass furnaces.

Dated October 21, 1869.

3063 S. H. Musgrave, Camden-road, Camden Town. The manufacture of needle and other cases from opaque glass tubing of various colours, fitted with a peculiar metal spring slide, scoop, and cap in one.

3064 H. Brooks, Cumberland Market, Regent's Park. An improved metallic cap or cover to glass or other bottles or vessels.

3065 J. Becker, Rue de Penthievre, Paris. An improved apparatus for stopping bottles.

3066 G. M. Ashforth, Market Overton, and W. Hardy, Thistleton, Rutlandshire. Improvements in obtaining and applying motive power applicable to working sewing machines and other useful purposes.

3067 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in rotary blowing engines.

3068 G. Clark, Southwell House, Lower Heath, Hampstead. Improvements in hansom cabs.

3069 G. Dauzats, Boulevard Bonne Nouvelle, Paris. Coloured or illustrated dominoes with central number.

3070 J. Buchanan, Gateshead-on-Tyne. Improvements in apparatus for coiling electric telegraph cables or ropes.

3071 F. Jenkin, Fittis Row, Edinburgh. Improvements n bridges.

3072 A. M. Clark, Chancery-lane. Improvements in hinges and hinge guards for railway carrriage and other doors, part of which improvements is applicable for warming and ventilating railway carriages.

Dated October 22, 1869.

3073 R. J. Goodbody, Charleville-square, Tullamore, King's County, and R. E. Donovan, Ashgrove House, Upper Rathmines, Dublin. A new or improved apparatus for roasting tobacco for snuff, also applicable for roasting, baking, burning, or drying coffee, malt, and other granular, pulverous, and vegetable substances.

3074 T. Gibb and C. Gelstharp, Jarrow-on-Tyne, Durham. Improvements in the construction of furnaces for calcining ores and other substances, and in the method of working the same.

3075 H A. Bonneville, Sackville-street, Piccadilly. Improvements in sewing machines.

3076 J. R. Grayson, Princes-square, Bayswater. Improvements in apparatus for clipping or shearing horses and other animals.

3077 C. E. Fuller, Sambrook-court, Basinghall-street, City. Improvements in machines for manufacturing brushes.

3078 J. Rignall, Bury St. Edmunds, Suffolk. Improvements in reaping machines.

3079 W. J. Rivington, Clerkenwell, Middlesex. Improvements in counting and registering apparatus.

Dated October 23, 1869.

3080 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved manufacture of metallic tiles or slates for roofing.

3081 C. A. Ofverberg, Finsbury, Middlesex. Improvements in filters and filtering apparatus.

3082 F. Woodward, Worcester. Improvements in apparatus for signalling and communicating on railway trains.

3083 J. and J. Cash, Coventry. Improvements in boxes or cases for preserving letters, papers, and other documents.

3084 R. Scott and W. M'Ivor, Addiewell, Mid Lothian. A process whereby the sulphuric acid residues produced in the refining of oleaginous and bituminous matters may be utilised and employed for the production of sulphate of soda and sulphide of sodium and black ash.

3085 F. S. Anderson, Cannon-street, City. Improvements in obtaining fuel and light from water.

3086 T. Deichmann, Chester-street, Belgrave-square. Improvements in preserving meat.

3087 T. Hydes and J. and J. E. Bennett, Sheffield. Improvements in propelling ships and other navigable vessels.

3088 A. B. Ibbotson and T. S. Sarney, Sheffield. Improvements in metallic keys or wedges for supporting and securing railway rails in their chairs, and a method of manufacturing such keys or wedges.

3089 T. Bevington and S. Courtauld, Spa-road. Bermondsey, and J. A. Norberg, Almorah-road, Islington. Improvements in machinery for breaking stone and ore, part of which improvements are applicable to hammers and pile-driving machines and other machines in which weights have to be raised and suddenly dropped.

3090 L. Meurin, Mount-street, Berkeley-square. Improvements in clocks and other instruments for measuring time.

Dated October 25, 1869.

3091 P. Walker, Bewsey New Hall, near Warrington, Lancashire. Improvements in means for rendering coal mines less injurious to those employed therein.

3092 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in sewing machine needles.

3093 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the manufacture of dry white lead and white lead pigment from metallic lead.

3094 W. W. Ladelle, Wraysbury, Buckinghamshire. Improvements in bleaching.

3095 J. H. Johnson, Lincoln's Inn-fields. An improved adhesive compound, and its application to stamps, labels, wrappers, envelopes, and other like articles.

3096 G. Ireland, Handsworth, Staffordshire. Improvements in nut-crackers.

3097 J. Edge, Madeley, Salop. Improvements in flat wire rope.

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, NOVEMBER 5, 1869.

THE NEW BLACKFRIARS BRIDGE.

TO-MORROW will witness the inauguration by Her Majesty of two of the most important metropolitan improvements of the present day. These are the new Bridge at Blackfriars and the Holborn Valley Viaduct. It is our purpose now to describe the former of these works; particulars of the latter will be found in the succeeding article.

Just one hundred years ago—in 1769—the first bridge at Blackfriars was completed, from the designs of Mr. Robert Mylne, the works having been commenced in 1760, and the designs having been selected from twenty others sent in competition to the corporation of the city. As of the past we remember it as the third of our metropolitan bridges—London and Westminster Bridges being respectively the first and second—and a fine piece of masonry it was. The arches were elliptical in shape, and were the first instances in England in which the form of the ellipse was substituted for that of a segment of a circle in a bridge. The total cost of the bridge itself, irrespective of the approaches, was £152,840. The introduction of the ellipse was considered an innovation, and gave rise at the time to a lively controversy, in which Dr. Johnson took an active part in opposition to Mr. Mylne, and in support of his friend Gwyn, who had a competing design. Succeeding engineers, however, have widely endorsed Mylne's principle, and with the utmost success in the construction of bridges with very flat gradients upon arches of very elegant contour. But Mylne's bridge had a radical defect which shortened its existence most materially, and this lay in the foundations, which, giving way, were gradually letting down the whole superstructure. As long as patching, propping, and lightening the roadway could keep the bridge together, it was resorted to, but when it became clearly manifest that there was a beginning of the end, then it was determined to have a new bridge. The old bridge was closed in June, 1864, when the work of demolishing the superstructure was commenced, and was continued for about eighteen months. In January, 1866, the works of the present elegant structure were commenced, from the designs of Mr. Joseph Cubitt, with whom is associated as joint engineer Mr. Henry Carr, Messrs. A. and P. Thorn being the contractors, and their engineer being Mr. F. W. Bryant, the present president of the Society of Engineers. Mr. Penrice has watched the work on behalf of Messrs. Cubitt and Carr.

The work of construction has been longer and more tedious than was anticipated, owing to the unforeseen difficulties encountered in removing the piers and foundations of the old bridge, which were of a very substantial character, although they were not carried sufficiently deep to ensure stability. Upon the works of demolition and reconstruction we need not here dwell, having paid occasional visits to the works, and having given our readers the benefit of our observations from time to time in reports of progress. These reports have also embodied the chief engineering features of the new bridge, so that we need now only describe it in general terms as it stands in its finished state. The structure is a wrought-iron rib bridge, each arch being composed of nine ribs, the contour of the ribs presenting a flat segmental curve. There are five arches, as will be seen from the engraving on page 334 of our present issue, which shows the bridge in elevation Two of the arches are of 155ft. span each, two of 175ft., and one—the centre arch—of 185ft. The height of the centre arch from high water level is 25ft., of the two next side arches 21ft. 6in., and of the two shore arches 17ft. The height of rise in the centre arch is 17ft., and in the others 16ft. and 12ft. respectively. The ribs are placed 9ft. 6in. apart; they are 3ft. 10in. deep at the crown of the arch, and 4ft. 7in. deep at the springing. The ribs are braced together at intervals of 17ft. Over them are laid the bearers, to which are bolted Mallet's buckled plates, upon which is a layer of asphalte 1in. thick. Over this again is a layer of broken stones and asphalte about 10in. deep, upon which is finally laid the granite pitching which forms the roadway. The total length of the bridge is 1,272ft.; its width, including the roadway of 45ft., and two footpaths of 15ft. each, is 75ft. The gradient is 1 in 40, less than half that of the old structure, which was 1 in 22. A row of handsome lamps is placed along each pathway, a little back from the kerb—a plan not adopted on any other of the Thames bridges; and they are so arranged as to facilitate the navigation after dark. The balustrade is Venetian-Gothic in design, which, in fact, is the style of the bridge generally. It is a perforated balustrade, arranged in panels of plain and twisted columns, and presents a very elegant appearance. Over the piers are granite recesses, having seats capable of holding about a dozen persons.

The bridge presents a very elegant appearance from the river, from which point of view its fine arches and piers are seen to excellent effect. Externally the piers are of grey granite; internally they are of brickwork built solid. The foundations of these piers are laid deep in the hard London clay. The method adopted was to sink a number of iron caissons 36ft. in length by 18ft. in breadth, which were forced down through the bed of the river until they became fixed. Four of these caissons placed side by side, with slight intervals between, and having their length lying across the stream, furnished the basis of each pier. At each end of this row of caissons was one of a triangular form, on which was reared the cut-water of the pier. Each pier, with its cut-water, thus required six caissons. These were sunk about 20ft. into the bed of the river, and were afterwards filled with concrete and brickwork, as also the intervening spaces. In addition to these permanent caissons, others of a temporary character were introduced, and the whole process involved the constant employment of divers, as well as of steam engines, the latter to pump out the water from the interior of the caissons. On this solid mass of ironwork, concrete, and brickwork was laid the combined brickwork and granite forming the superstructure of the bridge. Over each of the cut-waters, resting on ornamental Portland stone bases, and from the caps of each of which the arched ribs of the bridge spring, are columns of red polished granite from the Isle of Mull. The shafts of these columns are each 10ft. 6in. in height and 7ft. in diameter, each shaft being surmounted by a Portland stone capital. Each shaft is formed of three pieces of granite, each 3ft. 6in. in height and weighing about 10 tons. The blocks are wrought with mathematical accuracy and their faces polished with the greatest care, presenting a beautiful appearance. The capitals are extremely rich and happy in design, those on the up-river side being carved to represent river birds and plants, while the capitals on the opposite or down-river side are representative of marine life—gulls and seaweed. The treatment is very bold, and reflects credit on the sculptor, Mr. Phillips. The spandrels of the arches are filled in with iron lattice-work, decorated with floral bosses. The external ironwork is painted of a bronze green, relieved by the gilding of the bosses. The parapet of the bridge is also painted bronze green, with appropriate gilding. Rising from each of the abutments is a fine pedestal of granite, with carved cornice in Portland stone. Two of these flank each end of the bridge, and viewed from the roadway they have a fine effect, and when surmounted by statuary—as we presume they will be in course of time—they will present an imposing appearance. The ironwork used in the bridge—between five and six thousand tons in all—has been supplied by Messrs. Lloyds, Fosters, and Co., of Wednesbury, both wrought and cast iron forming excellent examples of the work turned out by that firm. The new bridge with the approaches, will cost altogether about £400,000, or at the rate of about £4 per superficial foot, and is thus one of the cheapest permanent bridges yet built in London. There has been no test used to prove the strength of the bridge, simply because the sectional area of the wrought iron under each part is ten times in excess of what is required for the most trying exigencies of metropolitan traffic.

Whether we regard the design of the structure or its perfect and rapid execution, we can only find room for praise, the greatest credit being due to the engineers and contractors engaged upon the work. It is undoubtedly one of the quickest—if not the quickest built permanent bridge across the Thames. It was not until January, 1866, that the work of construction was really commenced, and in the face of many impediments—want of room not being the least evil which had to be contended with—it has taken less than four years to complete it from first to last. Old Blackfriars was commenced in 1760 and finished, as we have said, in 1769, Vauxhall Bridge was begun in 1811 and finished in 1816, Waterloo Bridge was also begun in 1811 and finished on the 18th of June, 1817, the second anniversary of Waterloo, after which victory the bridge was called; Southwark Bridge took six years to build, Hungerford five years, old Westminster eleven, and new Westminster, from one cause or another, very nearly the same time. London Bridge took seven years before it was completed; so that in the present instance we have no cause to complain either of engineers or contractors. Especial credit is due to Mr. Bryant, who has had the carrying out of the work for the contractors, and who has successfully overcome many difficulties which arose in the course of the construction. The gantry, 80ft. wide, which ranged the whole length of the bridge and carried a double line of rail, and the travellers, some of them lifting 20 tons, were examples of his constructive skill. From first to last the bridge has been a success, and now forms an architectural monument as well as an engineering achievement of which the present generation may be proud.

THE HOLBORN VIADUCT.

THOSE persons who are only occasional visitors to the metropolis, and who may now be visiting it after a lengthy absence, will hardly recognise the spot where once Holborn valley was spread out to view, and where day by day an ever-increasing traffic put horseflesh sadly to the torture and human patience sadly to the rack. The change is great, and stands out as a magnificent improvement upon the system of roadways upon which traffic was conducted of old. The civic authorities have for some time past had in view the bridging over of this gulf, which was accountable for 50 per cent. of the accidents arising from persons being run over in the City during the year. In 1863 they prepared and deposited in Parliament plans for what is known as the Holborn Valley Improvement, and in 1864 the Act was passed. In 1867 additional powers were obtained, providing for the construction of a

street leading from Holborn, viâ part of Shoe-lane, to the foot of Ludgate-hill. The Holborn Valley Improvement, as set forth in the first Act, consists of the viaduct and two approach streets. The viaduct, bearing a roadway and foot pavements on its summit, extends across the Holborn valley from the western end of Newgate-street to the south end of Hatton Garden.

The approach streets afford a means by which vehicles can mount from the bottom of the valley to the summit of either hill. These streets are so arranged that the gradients are slight, bearing no comparison with the steep acclivities of the former Holborn-hill and Skinner-street. The western approach street is 500ft. in length by 60ft. in width, and starts from the top of Holborn-hill at its junction with Hatton Garden, proceeding in a north-easterly direction down the western declivity of the valley into the Farringdon-road. As this approach street descends the hill side obliquely the gradient is reduced to 1 in 45—an arrangement which is facilitated by the raising of a portion of the Farringdon-road, whereby the floor of the valley is elevated. This raising of the ground lessens the elevation of the bridge by which the viaduct crosses Farringdon-street. A little north of this bridge commences Farringdon-road, formerly only 60ft. wide, but now enlarged to the same width as Farringdon-street—namely 96ft. About 400ft. north of the viaduct bridge is the junction between Farringdon-road and the western approach street. At this point the new thoroughfare known as Charterhouse-street forms a continuation of the western approach street, and leads obliquely up the other side of the valley, still in a north-easterly direction, to the northern front of the new Metropolitan Meat Market. The eastern approach street is 50ft. wide, and has a gradient of about 1 in 45. It runs obliquely up the eastern side of the valley, starting from Farringdon-road at a point about 100ft. north of the viaduct bridge, and running parallel with the viaduct for a length of some 400ft. or more, taking, therefore, a south-easterly direction, after which it turns more towards the south, and finishes its entire course of 700ft. by joining the viaduct road at St. Sepulchre's Church.

These approach streets are thus confined to the northern side of the viaduct; the southern side is partially provided for by the Act of 1867. Provision is there made for one such street 50ft. in width and taking the western side of the valley from the south end of Farringdon-street to the top of Holborn-hill, passing at the back of St. Andrew's Church. The central part of Shoe-lane, for a length of 400ft., will be incorporated with this new thoroughfare. An entirely new portion, also about 400ft. long, runs from Holborn, at the back of the church, into this appropriated portion of Shoe-lane, which will be widened to 60ft., involving the pulling down of part of Farringdon Market. From the top of Stonecutter-street the new street will be carried diagonally across Harp-alley, a line of 500ft., terminating at the lower end of Farringdon-street, debouching towards the circus at the foot of Ludgate-hill. Having described the plan of the works generally, we will now proceed to describe the main structural feature of the scheme—the Viaduct. At the junction of the viaduct with Holborn-hill several thoroughfares open into a circus 170ft. in diameter. The thoroughfares radiating thence are the Viaduct-road, Western Charter-house-street, Holborn, and the new street leading down to Shoe-lane and the southern end of Farringdon-street, Hatton Garden, and Bartlett's-buildings. The viaduct is 1,400ft. in length and 80ft. in width, the carriage way being 50ft., and the two pathways 15ft. wide respectively. On the left just through the circus are examples of the buildings it is intended to erect along the viaduct. The first is the new establishment of Messrs. Negretti and Zambra, the opticians, and the next that of Messrs. Fearon and Son, the wine merchants, whose premises and vaults we described a few weeks since. Advancing eastward we pass on the right the church of St. Andrew's, Holborn, which is now approached from the roadway *down* a flight of steps instead of *up*, as formerly. From Hatton Garden to Farringdon-street, the viaduct has an ascending gradient of 1 in 143; from the latter point to St. Sepulchre's Church it descends at the rate of 1 in 153, after which the road is continued on to Newgate-street with a rise of 1 in 696, a very great contrast to the former gradients on this line of route. Not far beyond St. Andrew's Church is the bridge carrying the viaduct over Shoe-lane, whilst a little further eastward is the fine bridge over Farringdon-street. The bridge over Shoe-lane is tasteful and decorative in its style. It consists of one span, the girder and parapet being coloured so as to correspond with the Farringdon-street bridge. The main girders are of wrought iron, with cast-iron cross girders, carrying Mallett's patent buckled plates.

The viaduct crosses Farringdon-street obliquely, so that the bridge has a skew of 36deg. This bridge, which, in an engineering point of view, is the chief feature of the viaduct, is the point at which Mr. Haywood has concentrated his engineering and architectural strength. The bridge, of which we give a perspective elevation at page 335 of our present issue, is divided into a centre and two side spans, supported by twelve columns of polished granite and twelve abutment piers, the four external piers being also of granite, and the remainder of Portland stone. The granite columns stand six on each side of the roadway, dividing it from the pathways, and the abutment piers project from the side walls. The base of each column is of Cornish granite unpolished, the base moulding being of black Guernsey granite polished. The shaft, 4ft. 3in. in diameter, is of polished red Ross of Mull granite, and the capitals are of polished Aberdeen granite, ornamented with bronze leaves. Referring to the four external columns, we have to add to the foregoing that which comes above the capital, consisting of a block of polished Ross of Mull granite, continued up to form a pedestal for a statue. There are thus four statues, which appear as surmounting the parapet of the bridge. The figures face the roadway of the viaduct, and represent Art, Science, Commerce, and Agriculture. The statues are 8ft. high, cast in bronze by Messrs. Elkington, the artists being Messrs. Farmer and Brindley, for Art and Science, and Mr. H. Bursill, for Agriculture and Commerce. The height from the road level in Farringdon-street to the top of the pedestals bearing the statues is 31ft., that on the northern side of the bridge being slightly less owing to a difference of level. The headway under the bridge is 21ft. in the centre, and 16ft. at the sides. The iron girders and parapet of the bridge are painted bronze green, relieved with orange and gold. The spandrels of the arches are of open foliated ironwork, with the City griffin. The City arms appear on the parapet over the centre arch, whilst griffins surmount each of the smaller arches. On the parapet over the centre arch, above the City arms, is a lamp standard with three lights, a lamp standard of one light being fixed over the griffins of the side arches.

At each of the four angles of the bridge is a stone staircase, whereby foot passengers can ascend and descend to and from the viaduct. At each angle, also, a lofty building rises, each of which has a statue carved in stone on the front facing the viaduct roadway. At the south-west angle is Fitz Eylwin—better known as Fitz Alwyn,—the first Mayor of London. At the south-east is Sir Thomas Gresham; at the north-west is Sir William Walworth; and at the north-east the renowned Sir Hugh Myddelton. There is a recess between the windows of the first floor for each statue. The buildings are in the free Italian style, and are wholly of Portland stone. The sculpture is the work of Mr. Bursill. Continuing our course along the viaduct still eastward, we soon come upon the bridge which carries the roadway over the metropolitan extension of the London, Chatham, and Dover Railway, the parapet of which is close and high.

The interior of the whole of this vast pile of masonry, brick and ironwork, is utilised. It consists of extensive series of vaults, which are entered by gateways under the Farringdon-street and Shoe-lane bridges. These vaults are formed by arches springing from east to west. Those in the loftiest parts of the viaduct are the most commodious; but all are spacious, dry, well ventilated, and of a temperature almost uniform. As noticed by us a few weeks since, the whole of these vaults west of Shoe-lane have been taken by Messrs. Fearon for the storage of spirits, which is the first occupation on the route. Houses along the viaduct will be enabled to communicate with these vaults by corridors running across underneath the thoroughfare. Beneath each pathway are smaller vaults which are arranged in tiers, and which will afford cellarage for the adjacent houses. They are formed of arches springing from east to west, and about 10ft. span. Near Farringdon-street these vaults are three tiers in height, but the tiers gradually diminish east and west, as the ground rises according to the old level until, at the ends, they are reduced to one tier. Between these side vaults and the larger central vaults there is on either side a vertical space of about 7ft. wide, extending downward from beneath the carriage-way and footway to the foundations of the viaduct. Each of these spaces is divided into two storeys by an intervening floor of 6in. stone slab. The upper storey is the subway; the lower one is a tunnel for the sewer. In the centre of the viaduct, below all this, is the tube of the Pneumatic Despatch Company, through which the Post Office bags are whisked *en route* between Euston-square and the General Post Office. The great Holborn sewer, measuring 5ft. 6in. by 4ft. 3in., is diverted under Charterhouse-street so as to avoid the viaduct. The house vaults, the subway, and the sewer tunnel are in duplicate, occupying space along the whole length of the viaduct on each side of the great central vaults. The subway and the sewer tunnel are one over the other, beween the outside and the central vaults. Thus the viaduct has two subways and two sewer tunnels. The sewers are for the drainage of the adjacent houses, and also receive the water from the gulleys in the road, the latter discharging into the sewer by means of pipes. The ventilation of the sewer tunnel is provided for by means of pipes leading up the party walls of the houses, and opening above the level of the roofs. The sewer itself is an open one and is paved along both sides.

Turning again to the upper portion of the viaduct we have to notice in conclusion a few details, which although in themselves of secondary importance, yet go very far to complete the perfectness of the entire work. As has already been mentioned, the two sides of the viaduct will in course of time be lined with houses, and will form a street, the appurtenances of which are already supplied. These consist first of lamp-posts, which are of elegant pattern, and are coloured in bronze and gold in harmony with the Farringdon-street Bridge. Each of the lamp pillars is arranged at the base to contain a meter. Half-way up the pillar a disc plate is fixed, through which the gas supply pipe passes, to prevent any gas that may have escaped from the pipes in the subway ascending to the lighted lamps and so causing an explosion. Under the disc the pillar is pierced with

ventilating holes, to allow free vent for the leakage gas. The lamp heads are cylindrical in form. In the centre of the circus at Hatton Garden is a lamp standard of seven lights. A standard of five lights occupies the centre of the junction formed by the eastern approach street and the viaduct near St. Sepulchre's Church. At intervals along the pavement hydrants are inserted, three of which are for watering the roads. The remainder, 100ft. apart, are for the extinction of fires, and have been arranged according to the suggestions of Captain Shaw, the chief of the Fire Brigade. Cast-iron street orderly bins are placed at intervals, each capable of containing a truck load, the rubbish being put in at the top, and taken out at the foot, the whole remaining perfectly closed except when one orifice or the other is required to be opened. Pillar letter boxes are also added and complete the list of useful adjuncts.

Finally, let us say a word respecting those upon whom has devolved the task of designing and carrying out this great work of improvement. Most faithfully and well has the whole scheme been carried out by the executive. Mr. William Haywood, the city engineer and surveyor, deserves the highest credit for the design and arrangement of the whole work, which has been carried out under his superintendence. The excellent manner in which the general contractors, Messrs. Hill, Keddell, and Waldram have done their work is also evident. Although the viaduct has been constructed piecemeal, according as the land could be obtained, the several sections have ultimately been joined together without the slightest deviation in the lines. The work has stood firmly, not a crack or displacement appearing in any part. The Improvement Committee of the Corporation also deserve commendation for the trouble and anxiety so complicated an undertaking must have caused them. The contractors for the ironwork of Farringdon-street bridge are Messrs. Cochrane, Grove, and Co., and for the pipe-laying Messrs. Docwra and Son. The following portions of the work were executed by Messrs. Handyside and Co., of Derby, viz.:—The iron bridge and parapets over Shoe-lane, the iron subway, bridges, and parapets over the London, Chatham, and Dover Railway, the ornamental gates at the four entrances to the subways in the Farringdon-road, the bronze foliage on the capitals of the polished granite columns and abutments supporting the Farringdon-road bridge, and the ornamental lamp pillars on the viaduct and approaches. We congratulate all those who have been engaged in the work upon having brought so important an undertaking to a successful issue.

THE NEW ZEALAND MEDAL.

As considerable anxiety is naturally felt, in military and naval circles especially, in regard to the proposed distribution of medals to the officers and men who have shared in the various contests with the Maories during the past twelve or fifteen years, it may be as well to state that the dies for striking them are in course of preparation at the Mint. Some time, however, must elapse before the medals are struck, for the ordinary coinage has to be simultaneously carried on at that establishment, and medal making is at all times a tedious operation. For the sake of gratifying the curiosity of the public in general, and of the expectant warriors in particular, we shall describe the designs which ornament the metallic decorations. The obverse of the New Zealand medal bears as its principal device a bust of Her Majesty, and this covers the greater portion of the field. The royal head, which is cut in very bold relief, is completely draped at the back, the veil falling in ample folds to the shoulder. The face of the Queen may be considered as a successful portrait if a margin be allowed for a pardonable amount of flattery on the part of the artist who delineated it, and, as on the English coinage generally, it is turned towards the left. A supposed tiara of gold, in which diamonds and other precious stones are, imaginarily, set, and which as a whole is excellently engraved, rests gracefully on her Majesty's head, whilst strings of pearls and gems encircle the neck and rest upon an elaborately chased robe covering the breast.

The inscription on the obverse is lengthy, but the merit of originality can scarcely be claimed for its composition, as it is identical with that on the common British penny, viz.:—"VICTORIA D : G : BRITT : REG : F : D :" On the reverse, the victor's wreath of laurel—depicted with minute regard to the natural characteristics of the evergreen plant, and of skilful workmanship—forms the main feature. In the field, and within the wreath, the date appears. This, however, will vary on different medals, so as to identify their recipients with the campaigns of particular years. Above the wreath the words "New Zealand," in thin thread-like letters, but distinct and clear withal, are placed, and underneath appears the Latin motto *Virtutis honor* (which may be translated "honour to valour") in similar characters. The name, with rank or title of the owner, where either exists, will be indented on the edge, as in the case of the Crimean medals, with which, so far as diameter and weight are concerned, the new medals will be uniform. The material is to be silver, of a higher standard than that of the current coin of the realm, but not of virgin purity. The designs for both obverse and reverse are the work of the Messrs. Wyon, of Regent-street, who also prepared the matrices and puncheons from which the dies are produced. It is somewhat remarkable that these latter operations—artistic and manipulative—should not all have been performed within the Mint, which has its engraver, Mr. Minton, and its medallist, Mr. L. C. Wyon, and who are both men of talent.

RECENT LEGISLATION ON TURKISH MINES.

No sooner do men become thoroughly acquainted with the superficial character and contents of any district or country than they seek to penetrate beneath the crust and explore those hidden treasures which Nature for the most part conceals in her subterranean stores. In exactly the same degree and proportion in which these explorations are carried on, so does a nation rise to commercial prosperity and welfare. But for its mines, more especially its black diamonds, England would have been the most insignificant little island on the face of the globe! Its prosperity has been mainly due to its hidden wealth. On many portions of the earth mining industry is unknown, on many others still in its very infancy. This occurs even in countries which are ranked among the "Great Powers." The vast extent of Russia has been, in a subterranean sense, scarcely explored at all, and Turkey has done little or nothing in the working of her mines, which are unquestionably of great value and national importance. Many years ago this might have been put down to ignorance of their existence. It is true that some would be inclined to term it very culpable ignorance, but yet the excuse, however poor, could be alleged. Now matters are changed. Recent geological investigations, together with the information acquired by the introduction of railways, which has necessitated a more complete examination of the country than had been previously undertaken, have demonstrated that in both these countries there is an enormous amount of latent mineral resources. In the latter country especially there are numerous extensive metallic veins to be met with at the foot of the mountains of Epirus, and in the district contiguous to the great Balkan range of hills. The neighbourhood of Mount Pelion is rich in the galena or argentiferous lead ore of Thessaly, and copper veins abound near the shores of the fatal Bosphorus. Lethargic as Orientals invariably are when contrasted with their Western brethren, yet the mines in Asiatic Turkey are sufficiently valuable to induce the State to work them. From the silver mines the annual production is over seventy tons, while in the same locality a copper mine yields annually a thousand tons, and one of lead gives a couple of hundred. In addition to these may be mentioned the results of private enterprise and investment of capital. Copper mines, near Trebizonde, famous for its bees and their poisoned honey, and those at Fokat, yield on the average 700 tons per annum. A large proportion of this mineral wealth is exported, a great quantity of it finding its way to France. Besides metals, coal has been discovered in Asia Minor, at Smyrna, Aidin, and in the African possessions at Tripoli.

However little interest a government may display in the discovering or exploring of a nation's resources and natural wealth it nevertheless wakes up very quickly to their value and importance directly they have been discovered, with a great disregard to the agency by which the discovery has been brought about. One of the first steps to be taken in order to benefit commercially by the export of minerals is obviously to provide ports and harbours where the means of transport can proceed with safety and facility, and the intercommunication with other nations be conducted with mutual advantage and success. Turkey in this respect is not badly provided. Even if she has not the ports, at any rate she has the seaboard, which is the first essential. Her frontiers extend to the Danube. She touches both the Bosphorus and the Mediterranean, and her advantageous contiguity to these seas will be considerably enhanced when the railways in the interior part of the country are farther and more fully developed. About eight years ago, the government of the Sublime Porte, observing what a brilliant future in mining industry was open to the nation, determined to legislate in the matter and introduce those general principles which regulate similar branches of labour and enterprise in all civilised countries. With this object in view a commission was created and charged with the regulation, surveillance, and responsibility in all affairs of mining administration. By one of the enactments the power was given to any landowner to search as much as he liked, and in any manner he pleased, for suspected minerals on his lands; but he was forbidden to make over this search or the operations connected with it to another party without the especial sanction of the executive. Since the promulgation of this edict it has been rescinded, and the proprietor may call in anyone to assist his operations that he desires. In case a proprietor owns lands in which there are minerals, and refuses to allow them to be worked, the government reserves to itself the right to enter upon that land and work the mines in spite of the owner. It also can grant a concession to a third party to work mines whenever the owner of the soil is unwilling to do so himself, provided the concessionaire commences operations within six months after the granting of the concession, and pursues them vigorously and continually. Any infringement of these conditions is followed by the revoking of the concession. All the shackles that formerly hindered the development of the mineral resources of the country are removed by these regulations, but a still more important enactment was made in the year 1867. It ran as follows:—"Every Turkish subject, or foreigner being a subject of one of the powers signing the protocol promulgated in 1867 by the government of his Imperial Majesty who may ask for permission to own and work mines, may

obtain it on condition of conforming to the present and future laws of the country." This wise and politic arrangement will doubtless exercise a very great influence upon the future industrial aspect of Turkey. It must be borne in mind that this country is only just aroused to a sense of the importance and value of an intimate communication with her Western neighbours. The more she facilitates this intercommunication, the better for herself.

It must not be supposed that with the permission to own and work the mines, the jurisdiction of the government terminates. On the contrary, it extends to many minute details belonging to the subsequent methods and plan of operations adopted for opening up the mines. In the first place, the method of working is prescribed, and none other allowed to be used. This is decidedly an unwise regulation, and will tend very much to deter English capitalists from entering upon such speculations. Probably, so far as the Turks themselves are concerned, who like to have the way of doing work shown to them, it will do well enough, but everyone of our contractors, from the largest down to the smallest "ganger," likes to do his work his own way. It is his business to make the job pay, and he is not likely to allow of any interference with respect to the *modus operandi* he is to employ. So long as he does the work to the satisfaction of those who are concerned in it, it is nobody's business how he does it. That's his look out. A uniform arrangement has been adopted respecting the payment to be made by the concessionaire. Directly the firman for the concession has been granted, he pays down a sum of from £5 to £50 according to the assumed value of the property. The second payment is, in fact, a rent, and is paid annually, and is a fixed sum of three-halfpence per acre. This is paid to the proprietor of the land, or to the government if the property be on Crown land. The third payment is also an annual one, and is proportional to the produce of the mine. It varies from 1 to 50 per cent., and is collected by the State. A glance is sufficient to point out that these monetary arrangements are based upon a foundation nearly similar to that which prevails in France. There are special engineers appointed by the State to supervise the working arrangements in the mines. If, on the one hand, this savours a little of the interference of red tapeism, on the other it relieves the concessionaire of a large proportion of anxiety and responsibility on the score of accidents and misadventures.

THE MOUNT ST. GOTHARD RAILWAY.

WHATEVER local or even national interest may be excited on the score of a main line of intercommunication in a country comparatively so limited in extent as our own, it is a mere trifle to that created by a proposed new continental railway. In the latter case our parishes become provinces, and our counties separate kingdoms and nations. The traversing the barriers that Nature has in her inscrutable wisdom placed between different races is the important point in every scheme for uniting them in a closer bond of intimacy—important in a double sense, not only because it generally constitutes the great physical difficulty to be overcome, but also because the route selected will bestow more direct advantages upon the countries in which its termini are situated than upon others more remote from its course. It will be readily apparent that so soon as a line is projected to cross any of the great mountain ranges dividing the various portions of a continent, the interest of every separate State is at once involved. Contention becomes the order of the day, and each loudly proclaims its own right to the boon, while it shuts its ears to the petition of its neighbours. The two rival schemes at present in which the passage of the Alps is concerned are those *viâ* St. Gothard and *viâ* the Simplon. Locally considered, so far as we may regard Switzerland, Baden, and the shortest route to Milan, the former line is to be preferred to the other. If, however, we remove the Swiss interest in this route, there is very little to be said for it, as it presents no similar advantages for France, Belgium, or for the through traffic from England. On the contrary, the object of its promoters appears to be to divert the traffic altogether from the French companies, and, in fact, create a monopoly for themselves. A glance at the map, showing the course of the St. Gothard line, will at once demonstrate that it is not so well adapted to unite and benefit the great railway systems of the continent as its rival. In reality it consists of a couple of main lines. One commences near the Lake of Lucerne, and terminates at Bellinzona, a distance of eighty miles. The latter starts from the last-mentioned place and finishes at Chiasso, and is about thirty-five miles in length. Its connection with Milan is effected by a junction at Bellinzona with the main lines of Lombardy, which are continued to the ports of Trieste and Brindisi. The immediate effect of the new route would be to bring into closer *rapport* the north of Italy with Belgium, the southern parts of Germany, and a small portion of the coast of France, and it is asserted will rob the Mont Cenis line of its present traffic. This is a mistake, as it will not in any degree affect that route.

If a line from north to south be drawn passing by St. Gothard, it will cut Holland at its narrowest part, and traverse Rhenish Prussia, Bavaria, Switzerland, and Lombardy. This is not the most advantageous course for the proposed project, as will be seen by inclining the line to the east so as to cross the Alps, not at St. Gothard, but at Splugen. Starting from this point, and drawing a line parallel to the former, it will carry us into the States of Hanover, Germany, pass through Milan, and form the shortest route from the North Sea to the shores of the Adriatic. In close connection with our subject is a question which yet remains to be decided. It is whether Trieste or Brindisi is to be the great emporium for international merchandise. Some give the preference to the former, but we select the latter as the best adapted for the purpose. There is not the slightest doubt that one, or perhaps both, are destined to become gigantic cities of commerce. Brindisi has a magnificent and easily accessible geographical position. It is close to Alexandria, and has railway communication with nearly every part of the continent. Our French neighbours put forward Marseilles as a competing port with both Brindisi and Trieste, but it is not far enough away from home to act as a receiving port for large cargoes. It would, in the event of it rivalling either of them, be in the interest of the Swiss to pierce the Alps at the Simplon Pass instead of at St. Gothard. A conference is being held at Berne to investigate the merits of the two routes, and in a short time it may be expected that the matter will be decided.

TELEGRAPHIC NOTES.

THE first general meeting of the shareholders in the Falmouth, Gibraltar, and Malta Telegraph Company in connection with the Anglo-Mediterranean and British Indian Submarine Telegraph Company was held on Tuesday afternoon, at the City Terminus Tavern, Mr. John Pender in the chair. The report stated that the whole of the shares had been allotted, and the allotment money paid. The order for the cables had been given to the Telegraph Construction Company, and £80,000 paid on account. The laying of the cable of the British Indian Company would be finished in March next, and the Falmouth Company's cable would be laid in April or May, so that the whole line of submarine communication between England and India would be thus completed. The Chairman congratulated the shareholders upon the opportune time in which the company had been brought out, thus enabling the directors to make terms with the Government before the telegraph system had passed into its hands. Arrangements had been made with the Postmaster-General with reference to the transmission of their messages between London and Falmouth, and the directors had also obtained the promise of special wires for their traffic, with other accommodation at the metropolitan terminus, and the same facilities as those accorded to other telegraph companies. It was intended that their tariff of charges should be as low as possible, in order that the advantages of telegraphy should be brought within the reach of the poorer classes.

Mr. John Pender, who has taken a leading part in the establishment of submarine telegraphy with India, and is chairman of the British Indian and the Falmouth, Gibraltar, and Malta Telegraph Companies, proceeds to Egypt to represent these companies and the Anglo-Mediterranean and the Telegraph Construction and Maintenance Companies at the opening of the Suez Canal.

The number of messages which passed over the French Atlantic Telegraph during the week ended October 30 was 1,042, the cable charge thereon being £2,592, showing an increase of £956 on the preceding week.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

NEW WAY OF BRONZING—AMMONIA POWDER—TO MAKE ANILINE COLOURS SOLUBLE IN WATER.

A NEW way of giving the appearance of bronze, applicable to small articles of copper, has been introduced by M. Zalewsky. He simply dips them in melted sulphur, with which some lampblack is mixed. The effect, of course, will be to produce a layer of sulphide of copper. What the lampblack can do we have no idea. According to M. Zalewsky, the coating of sulphide of copper will take a good polish. The great trouble in the process, which otherwise looks reasonable enough, will be to remove the layer of sulphur from the casting or whatever may have been dipped.

Some time ago we noticed the announcement of a new explosive called "ammonia powder." Further information, now to hand, tells us that, in the manufacture of this powder, nitrate of ammonia is substituted for the nitrate of potash used in ordinary gunpowder. There can be no doubt that a powder of this composition must have a far greater explosive force than common powder, since the nitrate of ammonia on ignition will be entirely converted into gas. The chief objection to the use of nitrate of ammonia will be its very deliquescent nature, which will make it extremely difficult to obey the injunction "keep your powder dry."

The aniline colours, insoluble in water, may, according to Dr. Zinsmann, who publishes the process, be made to dissolve in that menstruum in the following way:—A solution of gelatine in acetic acid of about the consistence of syrup is first made, and the aniline colour in fine powder is gradually added, stirring all the time so as to obtain a homogeneous paste. The mixture is then to be heated over a water bath to the temperature of boiling water, and kept at that heat for some time. Colours in this state, if a very clear gelatine is employed, will be applicable to many decorative purposes. Bookbinders, paperstainers, and printers will find them useful. They may also, we read, be used to colour confectionery and soaps. Before they are used for confectionery, it will be well to make sure that no arsenic is present

IN the "Times" obituary column of the 27th inst. were recorded the deaths of nine persons whose united ages amounted to 759 years, giving an average of 84 years and 4 months to each. Of the number four were ladies, whose ages were 80, 87, 88, and 95; and five gentlemen, aged 80, 81, 82, and two 83.

PREVENTING BOILER INCRUSTATION.

EVERY steam user who has been troubled with scale in his boilers—and very few have not—has doubtless tried to effect its cure by means of one or other of the various boiler compositions before the public. Some may have succeeded; some, to our knowledge, certainly have not. This may have been owing to various circumstances; amongst others, that of using the proffered remedy without ascertaining its chemical fitness for the water in which it was to be used. It has been too much the custom to assume that a given boiler composition will prove perfectly effectual in every kind of water. This mistake has only been found out after fruitless efforts to remedy the evil, but which, by a discriminate selection, might have been cured. Steam users, however, who have hitherto been unsuccessful in preventing scale will be glad to learn that a very perfect remedy is now being brought before the public by Mr. Smith, of 204, High Holborn, London. This preparation is a powder composed of several ingredients which are very certain in their action in preventing scale and perfectly harmless in their effect upon the metal plates. It is now more than a year since Mr. Smith first brought out this preparation. During that time it has been used by a number of firms whose testimony to its merits we have seen. We select, from a number of testimonials, two from parties whose names are well known to our readers. The first is from Messrs. Merryweather and Sons, the steam fire engine manufacturers, who, under date of January 21, 1869, write:—"We have used your boiler composition in our steam boilers, and find it to surpass, in our estimation, all others that have hitherto been used by us. We find that half the stated quantity is quite sufficient to keep our boilers free from deposit."

The second testimonial, which is dated March 16, 1869, is from Mr. Field, the inventor of the boiler bearing his name, and is as follows:—"I am tired of trying various preparations supposed to prevent incrustation in steam boilers. As regards your own composition, I have as yet only given it a partial trial in the case of a large Cornish boiler, in which the incrustation was very stony. I examined this boiler after six weeks' use of your preparation, and found that the greater part of the incrustation had been dissolved or reduced to a state of powder. On washing some of the plates, the iron is plainly visible, and I am of opinion that the whole of the scale will be removed in course of time. I have not seen so marked an action with any other composition, and am much pleased with it, especially as I have looked for action on the iron, and found none whatever." Another firm writes that "it does not injure the slides or brass fittings of the engine." Upon this latter point—the action of the preparation upon metal,—we recently had a conversation with an eminent analytical chemist. This gentleman assured us that, after some months of varied and searching experiment, he could not detect the slightest signs of injurious action upon any of the metals which he had subjected to its influence under the most trying conditions. These highly favourable results, together with those no less favourable which are vouched for in practical working, lead us to predict that Mr. Smith's composition will come into general use and will prove of the highest value to steam users.

DR. LIVINGSTONE.

THE following letter relating to the illustrious explorer has been received in London:—Zanzibar, Sept. 9.—Dear Sir,—Mr. Henry M. Stanley addressed a letter, dated London, March 8, 1869, to my cousin, who is United States consul at this place, asking him to send you any news he might obtain regarding Dr. Livingstone; but he informs me that, under the consular regulations, he is not allowed to correspond with anyone on matters of importance except through the Department of State. Now, therefore, I, instead of him, have the pleasure to inform you that yesterday letters were received here by the British Consul from Dr. Livingstone, dated August 8, 1868; and, though I have not seen them, I learn from one who has that, at the time of writing, the Doctor was in good health; that for a year previous he had been exploring a section of country to the south of the Tanganyaka Lake, which contained many small lakes, which he claims to be the true sources of the Nile; that he had heard that two sets of supplies had reached Ujiji from Zanzibar for his use, but that he had not yet been there for them; that he would ask that a further supply might be sent there—and among the articles he wished were included nautical almanacs for the years 1869 and 1870—which looked as though he purposed remaining in the country yet a long time. He gave no hint as to his intentions for the future, or when he might be expected to come out; and his letters, written on scraps of paper begged from the Arabs who brought them to the coast, are said to be very meagre in regard to news.—Trusting this may prove of interest, I am, dear Sir, &c., JOHN F. WEBB.

REVOLVER CONTEST.

A COMPETITIVE trial has been carried out at the Arsenal range at Woolwich between the Adams revolver—the weapon in use in the British military service—and Colt's revolver. Both are breech-loading pistols, and the ammunition fired was partly furnished by the respective makers of the competing arms, and partly bought by Mr. C. Healey, of the "Engineer," the contest having arisen, we believe, out of some comments made in that newspaper. For rapidity two sets of 24 rounds were fired from each weapon, the Adams doing it in 1 minute 30 seconds and 1 minute 35 seconds; the Colt in 2 minutes and 2 minutes 10 seconds—superiority for Adams, 38 seconds. For accuracy the pistols were fired from a hand-rest, 24 shots each. The target made at 60 yards by the Adams was 5.45 inches; by the Colt, 8.62 inches. At 30 yards, Adams, 3.37 inches; Colt, 6.75 inches. For accuracy and rapidity combined the results were:—At 60 yards, Adams with 24 rounds, a target of 7.91 inches, in 2 minutes 32 seconds; Colt, a target of 11.70 inches, in 2 minutes 55 seconds; at 30 yards, Adams, a 5.62 inches target, in 2 minutes 5 seconds; Colt, a 5.16 inches target, in 2 minutes 5 seconds. The mean penetration of both weapons at 30 and 60 yards ranges was 3.33 half-inch boards for the Adams, and 2.66 for the Colt. But these last results are too evidently dependent upon the brand of powder used, and the respective degree of hardening of the bullets, to make it necessary to draw any grave distinction upon this point between the pistols themselves. The cartridges used throughout the trials were filled by Messrs. Eley, and have been commented upon for their faultiness of action. As the Adams pistol fires a Boxer cartridge of government dimensions, it is to be regretted the contest was not made with the service ammunition, as it was under the umpireship of the Arsenal Laboratory officials. The victory of the Adams revolver is, however, marked apparently beyond any possible fluctuation incident to ammunition.

THE INSTITUTION OF CIVIL ENGINEERS—PREMIUMS.

THE Council of the Institution of Civil Engineers have awarded the following premiums for papers read during the session 1868-9:—1. A Telford medal and a Telford premium in books (to consist of a complete set of the publications of the Institution) to M. Jules Gaudard, C.E., Lausanne, for his paper "On the Present State of Knowledge as to the Strength and Resistance of Materials." 2. A Telford medal and a Telford premium in books to William Shelford, M. Inst. C.E., for his paper "On the Outfall of the River Humber." *3. A Watt medal and a Telford premium in books to Zerah Colburn, M. Inst. C.E., for his paper "On American Locomotives and Rolling Stock." 4. A Telford medal and a Telford premium in books to Thomas Nesham Kirkham, M. Inst. C.E., for his paper "Experiments on the Standards of Comparison Employed for Testing the Illuminating Power of Coal Gas." 5. A Telford medal and a Telford premium in books to John Ellacot, M. Inst. C.E., for his "Description of the Low Water Basin at Birkenhead." 6. A Telford medal and a Telford premium in books to Professor David Thomas Ansted, F.R.S., for his paper "On the Lagoons and Marshes of Certain Parts of the Shores of the Mediterranean." 7. A Telford premium in books to William Henry Wheeler, M. Inst. C.E., for his "Description of the River Witham and its Estuary, and of the Various Works Carried Out in Connection Therewith for the Drainage of the Fens and the Improvement of the Navigation." 8. A Telford premium in books to James Robert Mosse, M. Inst. C.E., for his paper on "The Mauritius Railways—Midland Line." 9. A Telford premium in books to Imrie Bell, M. Inst. C.E., for his paper "On Sinking Wells for the Foundations of the Piers of the Bridge over the River Jumna, Delhi Railway." 10. A Telford premium in books to John Milroy, Assoc. Inst. C.E., for his "Description of Apparatus for Excavating under Water, and for Sinking Cylinders." 11. A Telford premium in books to Samuel Parker Bidder, jun., Assoc. Inst. C.E., for his paper "On Machines Employed in Working and Breaking Down Coal so as to Avoid the Use of Gunpowder." 12. A Telford premium in books to Charles John Chubb, for his paper "On Coal-Getting Machinery as a Substitute for the Use of Gunpowder." 13. The Manby premium in books to David Marr Henderson, Assoc. Inst. C.E., for his paper "On Lighthouse Apparatus and Lanterns."

The Council have likewise awarded the following prizes to students of the Institution:—1. A Miller prize to Edward Bazalgette, Stud. Inst. C.E., for his paper "On the Use of Concrete in Building Operations." 2. A Miller prize to Frederick Harry Mort, Stud. Inst. C.E., for his paper—"An Inquiry into the Nature and Causes of Some Discrepancies between Theory and Practice." 3. A Miller prize to Tristie James Ellis, Stud. Inst. C.E., for his paper "On the Artistic Design of Bridges." 4. A Miller prize to Thomas Robert Gainsford, Stud. Inst. C.E., for his paper "On the Construction of a Railway Tunnel or Covered Way at Bradford, Yorkshire, among Abandoned Coal and Ironstone Workings." 5. A Miller prize to Charles Henry Grey Jenkinson, Stud. Inst. C.E, for his paper "On Wrought-Iron Girder Bridges." 6. A Miller prize to George Henry Roberts, Stud. Inst. C.E., for his paper "On Reservoir Embankments."

* Has previously received a Telford medal.

THE AMERICAN STEAM BUREAU.

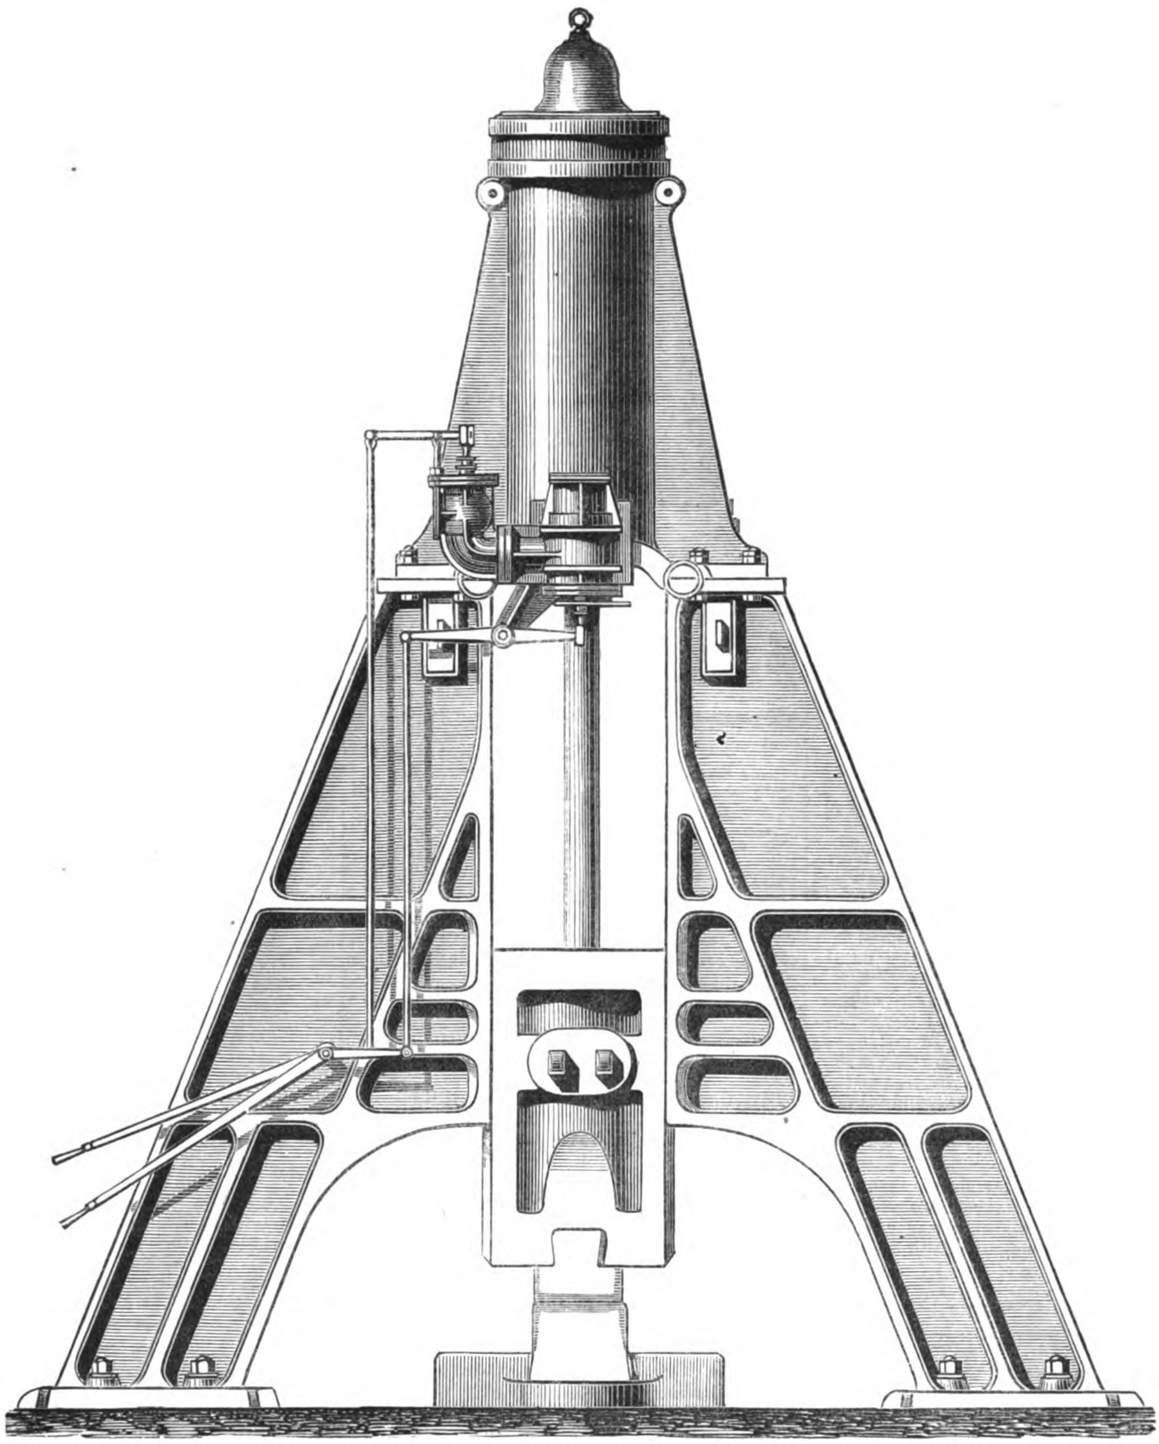
WE understand that the Board of Civilian Engineers, appointed by Secretary Welles in January, 1863, to make a thorough examination of the plans and doings of the Steam Bureau, have lately sent a synopsis of their report to Secretary Robeson, in answer to a request from him. This synopsis is nothing more or less than a condensed statement of the voluminous report they sent into Secretary Welles several years ago. It is astonishing how, in the face of so intelligent and convincing a report, the Department could go on, as it did, repeating and continuing the engineering monstrosities these impartial civilian engineers had so clearly pointed out. Many millions in money, besides the good name and efficiency of the service, would have been saved, had timely heed been given to their recommendations. The report seems to have been pigeon-holed, probably because it did not sustain and defend the projects of Mr. Isherwood, who was then all-powerful in the Department, and who was not prepared to listen to criticism. After going through a most searching investigation of the steam machinery of the navy, and carefully comparing it with the results and proportions of ordinary practice, the Board condemned the Steam Bureau's new-fangled theories and plans, without reserve or qualification. For instance, in referring to one class of screw vessels, they stated "that the power of the machinery for these vessels, by changes in type and detail, could have been increased at least one-third over that attainable by the Bureau's machinery, without adding to the space occupied, decreasing the coal stowage, or equalling the total weight or cost."

Now this is repeating, with the force of an official utterance, what this journal was at the same time carefully asserting in numerous articles. But neither the articles nor the report had the least effect in staying the ruinous course of the Steam Bureau. They were neither answered nor heeded: simply ignored.

An attempt was lately made to defend the abortive steam machinery of the "Wampanoag." What did these engineers say of engines of similar type and design, given them for examination six years ago, and long before the "Wampanoags" were begun? "By the use of properly designed, 'direct-acting' engines (in lieu of the geared engines proposed)," they reported, "an absolute saving of space, weight, and cost could be effected, while the power would be doubled and the speed of the vessel increased by at least three knots an hour." Yet condemned as they thus were in advance, and in terms so strong and definite, four or five "Wampanoags," costing nearly 2,000,000 apiece were built, and now stand as convincing proofs of the soundness of the criticisms and recommendations of this report, and sad evidence of the extraordinary fatuity of the Steam Bureau and the administration which could sustain it. In the lack of an intelligent and determined supervisory power, one self-confident man was enabled, in the face of the protests of the engineering profession, and in opposition to all sound practice, to experiment upon the National Navy, with the Treasury to pay his bills. We do not know how much the present Navy Department will be able to do in the way of remedying the evils entailed upon it, but we hope Congress will give its efforts every assistance.—U.S. "Army and Navy Journal."

EIGHT-TON STEAM HAMMER AT THE LANDORE STEEL WORKS.

BY MESSRS. THWAITES AND CARBUTT.



EIGHT-TON STEAM HAMMER.

THE accompanying engraving represents an elevation of an eight-ton steam hammer which has lately been erected at the Landore Steel Works, by Messrs. Thwaites and Carbutt, of the Vulcan Iron Works, Bradford. The hammer is for the purpose of hammering steel ingots before entering the rolls; this hammer, which is of the single-acting type, has a cylinder 30in. diameter and admits of a stroke of 7ft. The hammer head weighs eight tons. The cylinder is fitted with Messrs. Thwaites and Carbutt's cylindrical equilibrium valve, which is very simple and effective. The standards, which are H section, are made straight in form, and securely bolted to a massive bed-plate, and afford a good base for the hammer to stand upon. The anvil block for this hammer, which is cast in one solid piece, weighs seventy-five tons.

A STEAM FIRE ENGINE FOR VANCOUVER'S ISLAND.

THE important town of Victoria in this colony has a mixed population of English and Americans, the spirit of emulation being such that it possesses two volunteer fire brigades, which work in unison on the occasion of a fire. The American brigade already has a steam fire engine of American make, and the English brigade, to keep up its reputation, resolved also to procure a steam fire engine, and after having the designs of various English and American builders of fire engines submitted, selected a London engine of Messrs. Merryweather and Sons' make, the same as the engine "Le Prince Imperial," which gained the first prize gold medal at the late Paris Exhibition for these makers. The new engine for Victoria has a horizontal steam cylinder 6½in. diameter, and a direct and double-acting pump 5¼in. diameter, with 18in. stroke of steam and water pistons. The engine is made light, and is fitted with a lounge and rope reel, as it is for hand draught; is handsomely finished, and named "Deluge, No. 1." Previous to its shipment, it was thoroughly tested, and found to raise steam from cold water to 100lb. pressure in seven minutes from the time of lighting the fire. When in full work, its delivery of water is at the rate of 300 gallons per minute, projecting a stream to the height of 160ft.

SOCIETY OF ENGINEERS.

AT the ordinary meeting of the Society of Engineers, held on Monday, the 1st inst., in the Lower Hall, Exeter Hall, a discussion took place on a paper read by Mr. Perry F. Nursey, on October 18, "On English and Continental Intercommunication." The following candidates for elec-

tion were balloted for and duly elected, viz.:—As Members: Messrs. John Eunson, jun., engineer to the Northampton Gas Company; E. V. O. Haldane, late assistant-engineer, Hyderabad, Deccan; John Green Hall, city surveyor, Canterbury; Mathew J. Jennings, C.E., Durham Lodge, New Cross, Wm. Roebuck, Ellington-street, Arundel-square; Thomas Small, M.E., Gloucester; Robert P. Spice, consulting engineer, 21, Parliament-street; Thomas Warden, M.E., Birmingham; Thomas Wilkins, M.E., Orchard Works, Ipswich. As a Foreign Member: Lieutenant John Grierson, Bombay Staff Corps, lat. R.A. As an Associate: Samuel Cutter, jun., Providence Ironworks, Millwall.

MAKING FOUNDATIONS IN MARSHES.

A NEW process of making foundations for bridges in marshy soils has been recently used on a branch line of the Charentes Railway Company, in France. This line crosses a peat valley to the junction of two small rivers; the thickness of peat was so great that any attempt to reach the solid ground would have been very expensive. In order to obtain cheaply a good support for the bridge, two large masses of ballast accurately rammed were made on each bank of the river, and a third one on the peninsula between the two. The slopes of these heaps were pitched with dry stones, for preventing the sand from being washed away by the rain or by the floods in the rivers. Over the ballast a timber platform is laid; this platform carries the girders of the bridge, which has two spans of about 60ft. each. When some sinking down takes place, the girders are easily kept to the proper level by packing the ballast under the timber platform; this packing is made by the plate-layers with their ordinary tools. This simple and cheap process has succeeded quite well. The same difficulty was overcome by a different plan on an ordinary road near Algiers. This road crosses a peaty plain, nearly one mile broad; the floods and elasticity of the ground prevented the formation of an embankment. The road was to be carried over a viaduct across the valley, but the foundations of this viaduct presented serious difficulties, the thickness of peat or of compressible ground being nearly 80ft. It was quite possible to reach the solid ground with cast-iron tubes sunk with compressed air, or with any other system, but neither the implements nor the suitable workmen were available in the colony, and it was a great expense to bring them, and especially the workmen, from France. The use of timber piling was of course out of the question, as timber is very expensive in Algiers, and quickly becomes rotten; but there was a set of boring implements with the men used to work it. The engineers began boring holes 10in. diameter down to the solid ground. These holes, lined with thin plate-iron pipes, were afterwards filled with concrete up to the level of the ground. Each of these concrete columns bears a cast-iron column; these columns are properly braced together and support the girders of the viaduct, which is divided into spans of about 20ft., and is 20ft. high over the ground. This system has succeeded very well, and is to be extended to another large valley.

VARIETIES IN LEPIDOPTERA.*

By Mr. Joseph Sidebotham.

THE questions as to what constitutes a species? where does a species end, and a variety begin? and whether a species be a natural or merely an artificial division? are amongst the most difficult of solution in the whole range of natural history, and just at this time are very prominently before the scientific world. With a view to determine the influence which difference of food and light might have in modifying species, the author gives the following as the result of some experiments which he had made:—I procured about 2,500 larvæ of the tiger moth, in a young state. I divided them into six lots, keeping each in a separate cage, and feeding them differently. One lot was fed on willow, another on butter bur (*Petasites vulgaris*), another on hawthorn, another on plum, one on dock, and one on nettle, grass, bramble, and various other kinds of food. A considerable proportion of each became perfect insects, and I could detect no difference whatever in the colours, from the food they had lived upon. That is to say, the variations in colour and marking were not to be traced in any case to the food. I kept several batches of eggs, and reared the larvæ carefully through the winter, and then again divided them giving each lot a different kind of food. Again the same result. I found that one year the larvæ I had brought from the coast had usually the inferior wings more or less of a yellow shade, instead of the bright scarlet of the Cheshire specimens.

Having for many years continued these experiments without obtaining any marked results, I this year tried another of a different nature. I selected the tortoiseshell butterfly, as one of the least variable species we have, and I procured several broods of young larvæ just emerged from the egg. These I kept in a dark box until I had all ready, and then I divided each brood into three lots, putting one-third into a box in my photographic room, which is lighted with orange-coloured glass, one-third into a box lighted with blue glass, and the ventilators carefully shaded so that only light of a blue colour could reach the larvæ; the remainder were put into an ordinary cage, in the natural light. The latter fed up and came out into butterflies in the usual time. Those in the blue light were not healthy, and, though every care was taken, at least fifty or sixty died before changing, and a considerable number changed into chrysalides, and then died; those that came out into perfect insects were very much smaller than usual. Those lighted by orange-coloured glass fed up very well, but many of the two first lots had come out before one of them changed into chrysalis; scarcely one of them died, and I examined each one before I allowed it to fly, to see what effect had been produced.

Those reared in the blue light differ from the ordinary form in being on an average much smaller; the orange brown is lighter in shade, and the yellow and orange run into each other, instead of being distinct and separate. Those reared in the non-actinic, or yellow light, are also smaller, the orange brown is replaced by a salmon colour, the venation more strongly marked, and the blue dashes at the edge of the wings in the usual form are in these of a dull slatey colour. One evening I found about sixty butterflies out of chrysalis, of those in the photographic room, and taking each one carefully I examined them all and allowed them to fly; shortly afterwards I found the whole of them had settled against the wall of the house, and presented a most remarkable appearance; they remained there more than half-an-hour. The western sun was shining against the wall, and it is not unlikely when being suddenly brought from the red light, where they had spent all their lives, to the bright daylight, they were so dazzled as to act in this peculiar manner.

The results of this experiment do not show any very startling change in colour, such as one would have expected from the known effects of light on plants and from the occasional occurrence of very much more strange varieties one now and then meets with, which cannot have been subject to such severe treatment. Still, when we consider that even this difference is caused in one generation, and in the course of a month, it is a very suggestive fact, and leads one to think that light has certainly as much or more effect on the colours of Lepidoptera than the difference of food, and might in a long series of generations lead to very material changes in both form and colour, and perhaps considerably modify our ideas of what constitutes a species.

* Literary and Philosophical Society.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ON Monday evening last the open general meeting of the Royal Institute of British Architects for the present Session 1869-70 was held in Conduit-street. The President, Sir William Tite, M.P., delivered an inaugural address, in which he adverted to the increased prosperity of the Institute, both in regard to the number of its members and the state of its finances. He referred to the transactions of the past session, which had been of unusual importance, and to the interesting papers read by Mr. Layard, M.P., late Chief Commissioner of Works, and by Sir M. Digby Wyatt, Professor Donaldson, Canon Burgess, and others. After commenting on the late judicious selection of Professor Lepsius for the award of the Royal gold medal, annually presented by the Institute, with Her Majesty's sanction, to an eminent architect or *savant*, Sir William passed on to describe some of the more important architectural works of the day, especially mentioning the Holborn Valley Viaduct (by Mr. Haywood), Blackfriars Bridge (by Mr. Cubitt), the University of London buildings (by Mr. Pennethorne), and St. Thomas's Hospital (by Mr. Currey) as being eminently creditable to their respective authors. He congratulated the Institute on the care and success with which candidates for certificates of proficiency to act as district surveyors were now examined under the Metropolitan Building Act, and on the scheme of the voluntary architectural examination, which, as recently improved, was likely to encourage and benefit the architectural student, and he dwelt at some length on the great importance of an improved system of professional education. After the transaction of the formal business of the evening, the meeting was adjourned to the 15th inst.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

THE annual dinner of this society took place on Saturday last at the Restaurant, Westminster Chambers, the President, Mr. W. Forsyth Black, presiding. The usual loyal and other toasts were given, and success to the society followed, which was very cordially received. The president proposed the healths of Messrs. Roberts and Dawson, and spoke very highly as to the assistance they had given in working the society up to its present position, and for serving several years in the respective positions of honorary secretary and treasurer. It having been proposed at a previous meeting that the society's thanks should be given them in writing, advantage was taken of this opportunity, and a very nice illuminated engrossment on vellum was handed them by the president, which was acknowledged in a very effective manner. The testimonial is worded to the following effect, although separately:—

"That at a general meeting of the Civil and Mechanical Engineers' Society, held on the 23rd June, 1869, the following resolutions were unanimously adopted:

"To Frederick Hebberd Roberts, Esq., C.E., and George J. Crosbie Dawson, Esq., C.E.

"That the society accepts with much regret the resignation by Messrs. Roberts and Dawson of their respective offices of honorary secretary and honorary treasurer, and desires to express its high appreciation of the very efficient manner in which they have discharged the duties of their offices for the long period of nine years.

"That the society further wishes to convey to Messrs. Roberts and Dawson its best thanks for their zealous efforts to increase its numbers and extend its influence."

(Signed) W. Forsyth Black, President.
Arthur C. Pain, Hon. Treasurer.
William Meakin, Hon. Secretary.

The next meeting of the society is announced to be held on Wednesday, the 10th inst., at 7.30 p.m., at the society's temporary room at the Whittington Club, when some of the topics referred to by the president in his address to the members will form a subject for discussion.

TREATING WASTE LIQUORS.

AN improved method of treating the acid solution resulting from the operation of manufacturing tinned plates, and which has been saturated or partially saturated with iron from the plates or articles which have been dipped or steeped therein, has been patented by Mr. J. J. Vaughan, of Mitre Lane, Kensal Green. He subjects it either in an undiluted state or diluted below the crystallising point, or the residue or mother liquor remaining after the crystals of sulphate of iron have been deposited from the solution, to the following treatment:—A quantity of crude magnesite is pulverised and placed in the receptacle containing the liquor, which is allowed to filter through it, by which means the free sulphuric acid is neutralised. The filtrate is then treated with a further quantity of pulverised magnesite and subjected to heat, whereby the sulphuric acid of the copperas or sulphate of iron contained in the liquor is expelled therefrom and absorbed by the magnesia, the iron being left in the form of oxide. This process may be varied by treating the filtrate with calcined magnesite or magnesia so as to throw down the iron, the supernatant liquor being cleansed and boiled down, and the precipitated oxide of iron treated as may be required by drying or roasting to render it appli-

THE NEW BLACKFRIARS BRIDGE.

ENGINEERS, MESSRS. CUBITT AND CARR. (See page 327.)

cable for polishing, the manufacture of colours, and other useful purposes.

Another mode of treatment which may be adopted is to calcine the magnesia and to mix the before-mentioned solution with it, and then calcine or roast it after such mixing. The soluble sulphate of magnesia should be lixiviated and dried or crystallised, and the insoluble residue or oxide of iron dried and treated for the purposes to which the same is applicable. In the case of the acid residues resulting from the refining of petroleum and paraffin oil and other analogous materials Mr. Vaughan washes out or separates the acid as far as possible, and combines the same with raw or calcined magnesia, or the tarry "magma" is mixed with magnesia or its carbonate and roasted in a furnace with access of air. The resulting mass may either be purified or used in its crude state as an artificial manure.

MANUFACTURE OF IRON AND STEEL BY THE NITRATE PROCESS.

MR. J. P. BUDD, of Ystalyfera, near Swansea, has recently patented an invention which has for its object to subject molten cast iron to the action of nitrate of soda and soft hematite iron ore or other oxide of iron previous to its being subjected to the puddling process. For this purpose he runs the molten cast iron into shallow pans capable of holding from 3in. to 5in. in depth of melted metal and lined with a paste composed of the above-mentioned materials. When the fluid metal is poured into the pans a violent ebullition takes place and a large proportion of the silica, together with some of the carbon, phosphorus, and sulphur contained in the iron, is carried off in the slag, so that when the slabs of purified metal are subsequently worked in the puddling furnace the puddling operations are effected much more rapidly than with ordinary pig iron, as when puddling ordinary pig iron in a puddling furnace but a very small proportion of carbon is separated from the iron before the greater proportion of the silica is eliminated. Cast iron if of a suitable quality for steel making may advantageously be acted on by a paste containing nitrate of soda or hematite ore, or both combined, in shallow pans, as above described, previously to being decarbonised to convert it into steel.

When the object is to produce bars of wrought iron which are to be rolled into black plate or thin sheet iron to be afterwards converted into tin plate Mr. Budd lines the shallow pans into which the cast iron is run with a composition composed of hematite iron ore and nitrate of soda. He mixes together a quantity of hematite iron ore, containing if possible no phosphorus or sulphur and only a moderate quantity of silica, and mixes therewith half by bulk or two-fifths by weight of nitrate of soda, or 30lb. of hematite ore to 20lb. of nitrate of soda. Having well mixed these together mechanically the mixture is passed through a pair of clay rolls, by which the grit is reduced and it becomes more plastic. A paste is then formed of the mixture which requires about three-tenths of its weight of water to be added; it is then sufficiently liquid to be filled into a bucket. A series of shallow moulds of cast iron are then placed as near as convenient to the tapping hole of the blast furnace from which the fluid cast iron is to be obtained. Those found convenient are of the following dimensions:—Length, 7ft. 9in. at top tapering to 7ft. 4½in. at bottom; width, 2ft. 2in. at top tapering to 1ft. 9½in. at bottom; depth, 4in. The use of the bevelling or tapering in the mould is that the plate of cast iron shall be more easily removed from it. These moulds hold about 13cwt. of cast iron when filled about 3½in. deep. Into these moulds molten cast iron is run every 4 hours or oftener, care being taken to fill them often enough that they shall retain their heat or drying power between the casts.

As the casts from the furnace must thus be frequent the iron is potted from the furnace, that is, the operator takes out what iron he requires from an opening into the furnace at the upper part of the tapping hole without emptying the whole of the iron in the half. Whilst the moulds are hot from the previous cast he pours into each of them a bucket full or about 64lb. of the refining mixture before described and spreads it evenly over the bottom and sides. The water evaporates and the mixture lies at the bottom as an adhering paste. The workman then proceeds to run the molten iron from the furnace until he has filled the moulds about 3¼in. A great ebullition takes place, fumes in large quantity are evolved, jets of flame burn from the surface of the metal for a considerable time, a quantity of scoria is thrown up violently to the surface and separates from the plate of iron that fills the mould, and when cold can be stripped therefrom. The weight of the scoria so thrown up is from 30lb. to 40lb. from each plate of metal weighing about 13cwt. The iron contained in the hematite ore used in the paste is converted into cast iron and adheres to the bottom of the plate. The refined iron when broken presents a honeycomb or cellular appearance throughout and resembles overblown refined metal, and a large proportion of the silica will have been removed from it. The iron thus refined is ready for the puddling process.

As advanced refined metal Mr. Budd finds it advantageous to use some pig iron with the iron refined as above in puddling; about one-third of pig iron answers best. Cast iron thus refined, even if it be what is commercially known as cinder pig, which is produced when iron scoria are largely used as material in the blast furnace, will make excellent puddle bars and work to a good yield. The process of puddling is shortened, and the sides and the bottom of the furnace are less acted on than with unrefined iron. The quantity and proportions of the refining paste which we have given are suitable for the quality of cast iron known as white iron. When grey or carburetted iron is used the quantity of nitrate of soda to be used with the hematite ore should be increased; about 30lb. of nitrate of soda (instead of 20lb. as in the composition first mentioned) being used with 30lb. of hematite ore.

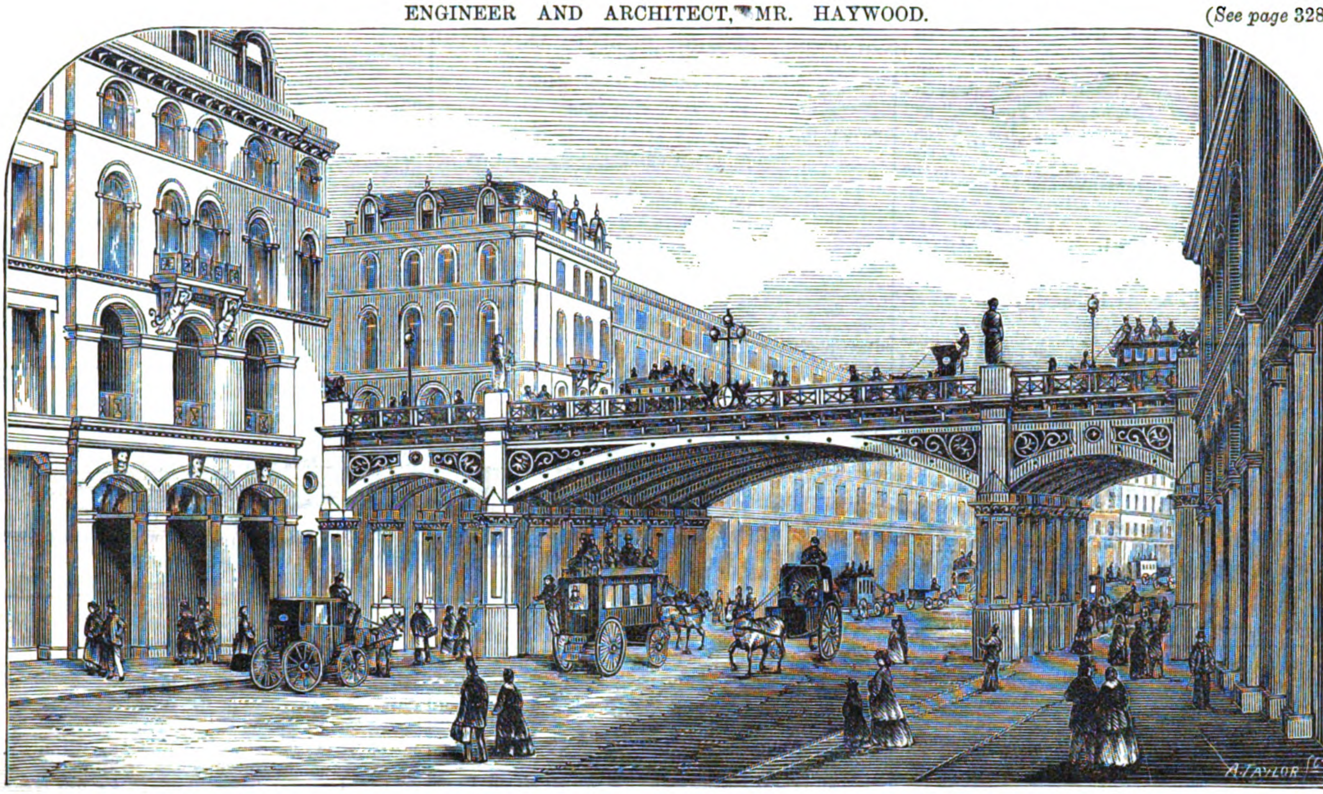
When the malleable iron sought to be made in the puddling furnace is not to be of the quality suitable for tin bars and similar purposes, but is required to be a softer working quality suitable for rails and merchant bars, Mr. Budd does not use nitrate of soda in the refining paste, but makes it of hematite ore alone. When used alone a great ebullition takes place when the molten iron runs over it, the oxide of iron in the hematite is reduced, jets of white flame burn on the surface for a considerable time, and a large proportion of the silica is separated from the iron. The refined iron in this state is much preferred by the puddlers, as it lessens and helps their work. In place of hematite ore other oxide of iron which can similarly be formed into a paste may be employed in place thereof, as, for example, the refuse of iron pyrites from which the sulphur has been extracted for the manufacture of sulphuric acid, and from which the copper and other metals contained in it have been extracted. Oxide of manganese, iron scale, or other substances capable of yielding oxygen when exposed to heat may be incorporated with the paste.

MESSRS. T. WINGATE and Co., of Whiteinch, have launched a composite screw of 620 tons, fitted with a pair of improved compound surface-condensing engines of 100-horse power. The steamer, which has been named the "Wilhelmine Emma," has been built to the order of Messrs. Miller Brothers, and she will proceed at once to Japan. The construction of the vessel is somewhat novel, the bottom being composite, with flush iron topsides, so as to combine in the highest degree the strength and stiffness of an iron vessel with the anti-fouling properties of a composite.

THE HOLBORN VIADUCT BRIDGE.

ENGINEER AND ARCHITECT, MR. HAYWOOD.

(See page 328.)

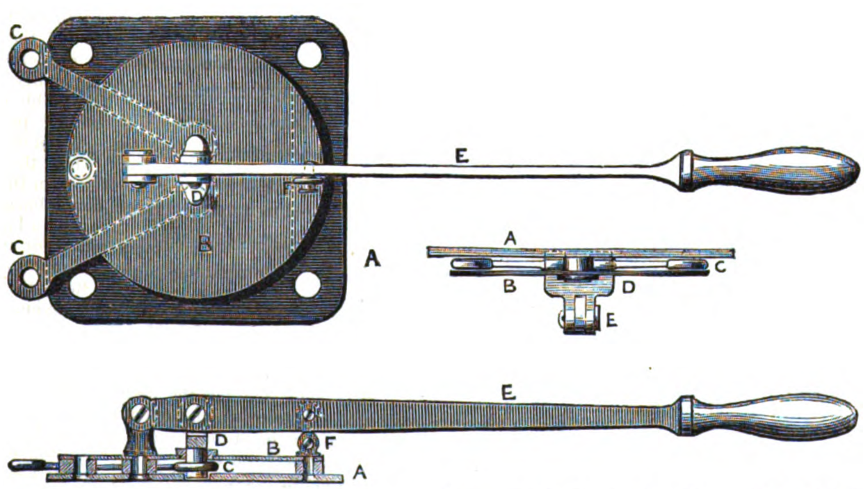


LAUNCHING LEVER.

A VERY ingenious instrument, for facilitating launches by dispensing with the mallet and chisel operation has been designed by Mr. W. B. Robinson, the master shipwright and engineer of Portsmouth Dockyard. This apparatus is seen in plan and section in the accompanying engraving. A is a back plate of wrought iron having four holes by which the instrument is secured to the rail of the launching stage; B is a guard plate to keep the links C C from lifting; C C are links to which the ends of the launching lines are attached; D is a fork slip bolt to hold the links C C until the vessel is ready for launching; E is a lever for lifting the fork slip bolt D; and F a hook to keep the lever E from being lifted by accident. By lifting the lever E, the links C C with the launching lines attached are released, and the weights fall on the dog shores. This ingenious contrivance, which is in. in length, was successfully introduced by Mr. Robinson, at the launch of H.M.S. "Dido," which took place at Portsmouth, on Saturday week. The "Dido" is an unarmoured 6-gun screw sloop of 1,268 tons burden and 380-horse power. She is built on the same lines as the "Danae," which was launched May 21, 1867. The "Dido" is a wooden-built vessel with rolled iron beams, and strengthening iron deck plating next to the waterways, and mid-deck stringer plating. Her principal dimensions are as follows:—Length between perpendiculars, 212ft.; breadth, 36ft.; depth in hold, 19ft. 4in.

LAUNCHING LEVER.

BY MR. W. B. ROBINSON.



TESTS OF BESSEMER RAILS.

THE best class of foreign rail manufacturers bear willing witness to the good character of the Bessemer steel rails made in the United States, especially those made by first-class houses like the Pennsylvania Steel Company, the Cleveland Iron and Steel Company, and the Freedom Iron and Steel Company at Troy. We believe that this favourable opinion is due to our home productions, as the managers of these prominent manufacturing houses omit no effort and spare no pains or expense to produce just such an article as will do the very best service in the track. The method of testing these rails is thus described by a circular issued by Messrs. John A. Griswold and Co., of Troy, and as efficient tests are made by the other establishments which we have named:—

1st. A test ingot from each five-ton ladleful of liquid steel is hammered into a bar, and tested for malleability and hardness, and especially for toughness, by bending it double cold. In case any test bar falls below the standard established as suitable for rails, all the ingots cast from that ladleful of steel are laid aside for other uses.

2nd. All the ingots, and each rail rolled from them, are stamped with the number of the charge or ladleful. A piece is cut from one rail in each charge, and tested by placing it on iron supports a foot apart, and dropping a weight of five tons upon the middle of it from a height proportioned to the pattern of rail. A blow equivalent to a ton weight falling ten or fifteen feet is considered a severe test. We use a five-ton weight falling from a less height, believing that it more nearly represents in kind (although it of course exaggerates in severity) the test of actual service in the track.

In case a test rail does not stand the blow deemed proper and agreed upon, the whole of the rails made from that charge or ladleful of steel are marked No. 2, and sold for use in sidings, where their possible breaking would do no great harm, and where their greater hardness and resistance to wear would be specially valuable. In addition to this double test, the rails are rigidly inspected for surface imperfections.

They further express the opinion that these tests render it practically impossible that rails of inferior quality should be sent out, and furthermore, they invite railway companies to send inspectors to their works to witness the tests mentioned, and other tests and inspections agreed upon. It is by the continuance of such rigorous tests and by proper quantities in case of breakage, that our manufacturers will command the confidence of railway managers, and command the respect of their foreign rivals and competitors. What is needed is a good article of rails, and railway managers may rest assured they will never get this unless they are willing to pay a fair price, and we beg to assure them that they are making a great mistake by buying cheap steel rails. Let them require a three years' guaranty, and they will find that the price will go up immediately. Every ton of cheap foreign-made steel rails that is purchased is a fraud upon the honest manufacturer, both home and foreign, while such purchases are a constant source of danger and expense to the railways. Managers had far better continue the use of iron rails than buy an inferior quality of steel. Let them rest assured that it is not economical or safe to buy either cheap iron rails or cheap steel rails.—"American Railway Times."

THE AMERICAN IRONCLAD FLEET.

THE ironclad fleet of the United States, although somewhat diminished in numbers since the close of the rebellion, still presents a formidable bomb-proof flotilla for coast defence, though somewhat rusty with age and hard knocks. Several of our best ironclads, says the "New York Tribune," are fully manned and equipped, and could be ready at a moment's warning, while the entire lot could be sent along the coast inside of a fortnight, should such a necessity arise. To give our readers some idea of the numerical strength of our walls of iron, we append a list of the present position of the ironclads. Those with a star prefixed carry four guns, those

with a dagger only one. The remainder carry two guns each, excepting the "Roanoke," which has six. At League Island are lying the †"Achilles," "Ætna," "Argos," "Atlas," "Charybdis," "Erebus," "Goliath," †"Gorgon," †"Hydra," "Jason," "Lehigh," "Medusa," *"Miantonomah," †"Nemesis," "Niobe," "Spitfire," "Tartar," and "Puritan,"—17, and one hulk. At New Orleans, the "Ajax," *"Cyclops," "Neptune," *"Samson," *"Tornado," and "Vesuvius"—6. At Mound City, the "Circe," "Fury," "Harpy," "Hecate," "Iris," "Minerva," "Tempest," and "Vixen"—8. At Washington, the 'Castor," *"Hero," "Montauk," and †"Orion"—4. At San Francisco, ready for action, the *"Monadnock," and "Comanche,"—2. At the Naval Academy, the *"Amphitrite"—1. In the North Atlantic Squadron, the "Centaur" and "Dictator"—2. At Boston, the "Terror," ready for sea, and the "Eolus" and *"Stromboli"—3. At Philadelphia, the "Passaic" and "Scylla," ready for sea—2. The following vessels are in process of construction: "Thunderer," at Portsmouth; *"Colossus," at New York; *"Hecla," at Philadelphia; *"Herculese," at Boston; and the "Niagara" is being converted into a broadside vessel at Boston—5. The "Roanoke," with her three turrets, is in ordinary at the Brooklyn Navy-yard—1. Total, 50. The torpedo boat "Spuyten Duyvil," is at the Brooklyn Navy Yard, and is a most terrible engine of warfare, not so much to look at as to encounter. It is not to be expected that a majority of these vessels could fight in a seaway; but as they were originally designed for coast defence, it is probable they would be assigned to such duty.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, November 4.)

CHEMICALS.—In chemicals there has been a fair amount of business transacted, and, still excepting the alkali trade, a more generally cheerful feeling is exhibited amongst the producers, and prices are tending upwards. In the mineral market some derangement has been occasioned by the late stormy weather, though not to any material extent affecting prices. Metals continue very inactive, and there has been but little doing. As anticipated, an amicable arrangement has been concluded with the ironworkers in South Staffordshire, and this source of uncertainty being removed, it is hoped that no check will be experienced to the late increasing business. Soda: prices remain the same for soda ash, at £7 to £7 5s. for 48. Caustic: rather more inquired for at £13 12s. 6d. Crystals inactive, at £4. Bi-carbonate is again in little request at £9 10s. Nitrate of soda: some sales at 16s. 6d. to 17s. Potash: a large amount of muriate on contract has changed hands, and business has been done at £7 5s. to £7 7s. 6d., for 80. Saltpetre: Bengal, 22s. 3d. to 23s. 6d.; English refined, 27s. Alum: there has been a considerable home demand for this article, which, coupled with some large foreign orders, tends to stiffen prices, though it is still held at £6 5s. for loose lump, and £7 in export barrels. Ammonia: sulphate continues to command high prices, and meets with ready sales, at from £15 for inferior to £17 10s. for 24. Copperas: in green and rusty sales are limited, at 52s. For dry there is an increasing demand, at £2 10s. Chloride of iron steady, at 52s. Pyrites: maintain late quotations, 7d. to 8d. per unit. Calcined still inquired for, at 44s. 6d. to 44s. R.C. Lime: phosphate meets with a rather better market, at 52s. 6d. for 65. Bleaching powder in more request at £8 5s. to £8 10s. for 35. Disinfectants are receiving increased attention, at 5s. 3d. per cwt. Manganese: very quiet at 95s. for 70. Acids: in tartaric a fair business, at 1s. 1½d. foreign; English ground, 1s. 2½d.; citric little doing, at 2s. 5d; oxalic at 7½d.

METALS.—Iron: Scotch pigs steady, at 53s. 6d. to 53s. 7d. Cleveland firm, at 44s. for forge to 49s. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire, £6 15s. to £7; Gas tubes at 60 to 70 off list; Boiler tubes, 40 to 45. Copper: is rather firmer. English ingot £71 10s. to £73; Chili Slab £67 10s. to £68 10s. Tin: very quiet. English £122 to £123; Straits £124. Lead is selling freely, and prices are firmer. P.G. best English soft pig lead, £18 15s. Spelter: dull. English £20 10s. to £21. Silesian, special brands, £20 5s. to £20 10s.; Hard spelter, for export, £16 5s. to £16 10s.

LIEUT.-GENERAL PHILIP SANDILANDS died at Hythe, Kent, on Saturday last, in his 80th year. The deceased officer entered the Royal Regiment of Artillery October 4, 1806, and became lieutenant February 1, 1808. He served with the expedition to Walcheren, also in the campaign of 1815, and was engaged on the 17th June with the Horse Artillery in covering the retiring movement from Quatre Bras, and on the 18th of June he was present at the battle of Waterloo.

Legal Intelligence.

COURT OF CHANCERY, WESTMINSTER.

NOVEMBER 2.

(Before the LORD CHANCELLOR.)

PARKES v. STEVENS.

THIS being the first day of Michaelmas Term, his Lordship, according to custom, took his seat at Westminster.

The above case was a motion for a new trial of certain issues tried before Vice-Chancellor James, affecting the validity of a patent taken out by the plaintiff for gas lanterns of a spherical form, such as are suitable for suspension in railway stations and other public places. The great object of the improvements effected by the plaintiff was to produce a glazed lamp, the frame of which should throw little or no shadow, and yet possess the requisite strength, and also facilities for lighting and cleansing the lamp. The latter object the plaintiff had effected by forming the upper half of each lamp of six panes of glass, each section forming the section of a sphere, and by making the door of the lamp of one of the six panes, which opened by sliding on a frame within the next pane, and not outwards on a hinge in the usual manner. The defendant had copied the plaintiff's lamps in those which he had erected in New Palace-yard, and the plaintiff had consequently filed this bill to restrain the defendant from infringing his patent, but his Honour decided that the sliding door was not sufficiently claimed by the specification of the plaintiff's patent and also could not be a valid subject of a patent. From this decision the plaintiff appealed.

On the appeal being resumed on Wednesday morning, the appellant having been heard, his Lordship directed the case to stand over till next motion day, when he would decide whether or not to call on counsel for the respondent.

Mr. Webster, Q.C., Mr. E. E. Kay, Q.C., and Mr. Everitt are for the appellant Parkes; and Mr. Amphlett, Q.C., and Mr. Bagshawe for the respondent Stevens.

Correspondence.

PUBLIC WORKS, INDIA, AND CIVIL ENGINEERS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

THE Secretary of the Institution of Civil Engineers presents his compliments to the Editor of the MECHANICS' MAGAZINE, and will feel obliged by the publication of the enclosed documents relating to a branch of the public service in India.

I.

Extract from the minutes of the Council of THE INSTITUTION OF CIVIL ENGINEERS.
THURSDAY, OCTOBER 21st, 1869.

"The Council proceeded to take into consideration the following extract from 'The Gazette of India,' September 4, 1869:

PUBLIC WORKS DEPARTMENT.

NOTIFICATIONS.
ESTABLISHMENT.
Simla, the 31st of August, 1869.

No. 242.—Whereas the Governor-General in Council is given to understand, that in the civil engineering profession in England, it is a recognised practice for civil engineers employed by public companies and otherwise, to receive, in addition to the salaries paid them by their employers, commission on contracts given out, or stores and materials ordered or inspected by them, and other like pecuniary considerations for services done, or intended to be done, which are considered legitimate sources of emolument; and whereas a considerable number of civil engineers, who have practised in England, have lately been employed by the government of India, and the number of such engineers is likely to increase;

1. It is hereby notified for general information that every person in the service of the government in the Public Works Department in any part of British India, whether civil or military, must consider his salary or pay, as regulated by the rules of the department for the time being, or defined in any agreement with the Secretary of State for India in Council, and whether it is drawn wholly or in part in the Public Works Department, or the Military Department, to be his sole legal remuneration; and that the receipt of commission, or any other consideration whatever, directly or directly, on account of any in business or transaction in which he shall be concerned in behalf of the government, whether in India or elsewhere, is prohibited.

2. Every officer of the government is bound to report to his departmental superior every infringement of the above rule which may come to his knowledge.

(Signed) R. STRACHEY, Colonel, R.E.,
Offg. Secretary to the Govt. of India.

"It was resolved unanimously:

"1. That this Council, on behalf of the Institution of Civil Engineers, incorporated by Royal Charter, and representing the profession generally, emphatically deny that, 'in England, it is a recognised practice for civil engineers employed by public companies and otherwise, to receive, in addition to the salaries paid them by their employers, commission on contracts given out, or stores and materials ordered or inspected by them, and other like pecuniary considerations for services done, or intended to be done, which are considered legitimate sources of emolument.'

"2. That the Council assert that any civil engineer detected in such practices would be held by the profession to be guilty of disgraceful conduct, which would disqualify him from being a member of this Institution.

"3. That it is deeply to be regretted that so grave a charge should have been received and published by the government of India without proper inquiry; as such inquiry would have shown that the charge was absolutely untrue.

"4. That such an imputation, stamped as it is with high authority, is calculated to do grievous wrong to an honourable profession, and has created a deep and general feeling of indignation.

"5. That the Council appeal with confidence to the government of India to cause the scandalous statement contained in the preamble of the notification No. 242 to be withdrawn.

"6. That the Council request the President, on behalf of the Institution, as representing the profession, to transmit copies of these resolutions to the Secretary of State for India, and to the Governor General of India."

Signed on behalf of the Council,
CHARLES HUTTON GREGORY,
President.

A true extract.
JAMES FORREST,
Secretary.

October 23rd, 1869.

II.

THE INSTITUTION OF CIVIL ENGINEERS.
Established 1818.—Incorporated by Royal Charter 1828.
25, Great George-street, Westminster, S.W.,
October 23rd, 1869.

My Lord Duke,—I have the honour to lay before your Grace the enclosed extract from the minutes of the council of the Institution of Civil Engineers, in reference to the notification No. 242, published in "The Gazette of India," in which it is implied that professional dishonesty is a practice which is recognised as legitimate by the civil engineers of this country.

I hope that our profession is sufficiently known to your Grace to render any official contradiction unnecessary to exonerate us in your opinion from such a charge. But the public at large can hardly suppose that such a statement could have emanated from the government of India without satisfactory proofs of its truth; and I cannot exaggerate the feeling of indignation which has been aroused by the notification among civil engineers of this country, and those engaged in India.

I have been requested by the Council to ask your Grace to be so good as to give us an audience upon this subject at your earliest convenience. Meanwhile, I beg to assure your Grace that we feel the utmost confidence that we shall not look to you in vain for such measures of justice as may authoritatively clear our profession from the disgraceful imputation which has been authoritatively fixed upon us.

I have the honour to be,
My Lord Duke,
Your Grace's most obedient servant,
CHARLES HUTTON GREGORY,
President.

To His Grace the DUKE OF ARGYLL, K.T.,
&c., &c., &c.,
Secretary of State for India.

III.

THE INSTITUTION OF CIVIL ENGINEERS.
Established 1818.—Incorporated by Royal Charter 1828.
25, Great George-street, Westminster, S.W.,
October 27th, 1869.

My Lord Duke,—Having reference to the inter-

view your Grace was this day pleased to accord to the deputation of the Institution of Civil Engineers, I am desired by the Council of the Institution to state in writing for your Grace's more specific information :—

1. That the profession does not recognise the acceptance by civil engineers of commissions, or other payments, except openly and directly from their immediate employers.

2. That the profession distinctly discountenances, repudiates, and condemns the practice implied in the notification No. 242, recently issued by the Public Works Department of the Government of India.

3. That it is a rule of the Institution not to receive into membership any person tainted, or believed to be tainted, by any of the improper and corrupt practices alleged in such notification.

4. That if it be possible to cite instances of misconduct by persons calling themselves civil engineers, yet that any such instances are entirely exceptional, and amount to flagrant departures from the well understood and well recognised practice of the profession, and, therefore, cannot justify the broad accusation contained in the notification in question.

I have the honour to be,
My Lord Duke,
Your Grace's most obedient servant,
CHARLES HUTTON GREGORY,
President.

To his Grace the DUKE OF ARGYLL, K.T.,
&c., &c., &c.,
Secretary of State for India.

IV.

THE INSTITUTION OF CIVIL ENGINEERS.

Established 1818.—Incorporated by Royal Charter 1828.

25, Great George-street, Westminster, S.W.,
October 28th, 1869.

My Lord,—I have been requested by the Council the Institution of Civil Engineers to transmit to your Excellency the enclosed copies of an extract from the minutes of the Council, and of two letters written by me on their behalf to the Secretary of State for India.

I beg to request your Excellency's serious consideration of a question vitally affecting the honour of our profession, in the assurance that you will be anxious to do us the justice which we respectively ask from the government of India.

I have the honour to be,
My Lord,
Your Excellency's most obedient servant,
CHARLES HUTTON GREGORY,
President.

To His Excellency
THE EARL OF MAYO, G.M.S.I., K.P.,
&c., &c., &c.,
Governor-General of India.

V.

INDIA OFFICE.

October 29th, 1869.

Sir,—I am directed by the Duke of Argyll to acknowledge receipt of your letters of 23rd and 27th inst., protesting on behalf of the Institution of Civil Engineers against an imputation considered to have been made against the British Engineering Profession in a notification of the government of India, wherein it is assumed to be a "recognised practice" in England "for civil engineers employed by public companies and otherwise to receive, in addition to the salaries paid them by their employers, commission on contracts given out, or stores and materials ordered or inspected by them, and other like pecuniary considerations for services done, or intended to be done, which are considered legitimate sources of emolument."

In reply, I am directed to state that the Duke of Argyll will immediately communicate with the Governor-General of India on the subject to which these letters relate, desiring to be informed of the circumstances which led to the issue of the notification in question.

His Grace considers it almost superfluous for me to add that he regards with implicit confidence the indignant repudiation by the Institution of any recognition of the practice referred to in the notification.

I am,
Sir,
Your obedient servant,
M. E. GRANT DUFF.

C. H. GREGORY, Esq.

SUN SPOTS.

SIR,—I perceive by a letter in your issue for the 22nd ult. that the writer, Mr. H. Saloway, is of opinion that the spots in the sun are due to the relative positions of the planets. If, as Humboldt remarks, the aurora is an indication of a highly excited state of the earth's crust, rendered visible under favourable circumstances in the upper regions of the atmosphere, it seems to be due to the action of the planets on the fluid interior of the globe. This is the more likely if we consider their attraction to be equivalent to a resisting medium, which by diminishing the velocity of the earth, must also cause it to part with a portion of its internal heat, as well as alter the plane and axis of its orbit. The periodic time of Jupiter, the largest of the planets, coincides with the period of those spots, say ten 1-10th years. Venus likewise, by her proximity to the earth, causes considerable alteration. When Venus was in aphelion and distant 45deg. from Jupiter, and the sun in square to Saturn, on March 8 and 9, I find there were several consecutive displays of the aurora, which is generally found to occur on the appearance of those spots. Again, on April 17, a display took place, the sun being in conjunction with Jupiter and Venus not far from the latter planet, and in trine to Saturn and Mars. Again, on May 16, Venus being close to the sun and in square to Mars and near her greatest illumination, a similar display occurred. Lastly, in September, from the 5th to the 10th, several displays took place, Venus being 144deg. from Jupiter, and the latter stationary towards the latter day; the same planet being also in square to Uranus. This, I think, proves that these planets exercise some influence on the sun in connection with the earth; and the nearer they are to the equator the greater this influence, whence the greater frequency of the phenomenon in the spring and autumn; the attraction of those planets being at this time exercised on the protuberant matter at the equator.

Another matter, which seems to deserve attention in connection with this subject, is that the readings of the meteorological instruments in such seasons are higher than the average. The mean height of the barometer, thermometer, dew point, relative humidity, mean range, and mean velocity of the wind are higher during such seasons than usual. This was so in the autumn of 1849. The mean of the eight weeks, from March 17 to May 18, was as follows:—Barometer: mean height, 29·989in.; mean temperature, 48·2deg.; dew point, 39·7deg.; relative humidity, ·8deg.; amount of cloud, 7·2deg. Thermometer: minimum, 41·9deg. (mean); maximum do., 58·6deg.; mean velocity hourly, thirteen miles; amount of rain, 2·846in. These figures are higher than usual considering the very wet autumn and mild winter which preceded this spring, when from analogy we should expect a very cold spring, as was the case in 1769. These spots would, therefore, seem to exercise a favourable influence on the weather, rather than otherwise. In 1867, I find that those spots were at a minimum, and the winter of that year was in marked contrast to that of 1869, being marked by excessively cold weather and a comparatively low barometer, the minimum of the thermometer being in January 1deg. against 32·9deg. in the present year; and otherwise distinguished by comparatively low readings of the instruments. The mean readings of this year, as contrasted with the above, were—barometer, 29·911deg.; thermometer: maximum, 67·6deg.; minimum, 31·8deg.; mean, 48·7deg.; mean daily range, 14·8deg.; rain, 22·472in.; number of rainy days, 164.

I would also refer to the same cause the sudden variations of temperature which we have experienced this year, rather than to the motion of the earth through regions of space of different temperature.—I am, Sir, yours, &c.,

DANIEL P. BROWNE, M.A.

Cork, October 27.

THE MONCRIEFF SYSTEM.

SIR,—In your publication of the 29th ult, I see a letter accompanied by a drawing entitled "The Moncrieff System Anticipated." Now, I cannot but think that this title is both very unjust to Captain Moncrieff and exceedingly misleading to the public. The invention described in the letter only very partially accomplishes the ends attained by the Moncrieff carriage. The gun is lowered below the parapet by the discharge, but there is no provision to store up and utilise the force of the recoil to raise it again, and this is a most important and essential feature of the Moncrieff carriage. The mechanical principle by which Captain Moncrieff attains his object, viz., a moving fulcrum, does not seem remotely hinted at. In fact, the carriage described by your correspondent seems no more worthy of being called an anticipation of the Moncrieff carriage than the Æolopile of Hero of Alexandria can be called an anticipation of Watts' condensing steam engine.

The carriage is but a mechanical appliance that makes the system proposed by Captain Moncrieff and partially explained in your columns possible. No system appears suggested by the inventors of this self-lowering but not self-raising carriage. It is specially unfair to speak of the whole system with its manifold applications suggested by Captain Moncrieff, and made possible by him, as only coextensive with the invention of a gun carriage.

Moncrieff batteries, where each gun is in a pit or semicircular excavation, are peculiarly sheltered from enfilade, except at the moment of exposure, which would rarely give the enemy time to lay his guns. The shells loaded with molten iron should at least find their way into the pit before they could burst and set fire to the platform, and to accomplish this would be no easy task.—I am, Sir, yours, &c.,

JAMES WHITE, M.A.

November 3.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

TUES.—Institution of Civil Engineers.—Discussion upon Mr. Ellacott's paper on "Description of the Low Water Basin at Birkenhead"; and on "The Present State of Knowledge as to the Strength and Resistance of Materials," by M. Jules Gaudard, C.E., at 8 p.m.

Naval, Military, and Gunnery Items.

A MUSEUM of books, portraits, and relics, commemorating the great siege, has just been opened at Sebastopol by General von Todleben.

THE mechanics in the smithery at Chatham Dockyard have commenced forging the stem and preparing the other ironwork for the iron-clad steam ram "Rupert," which is ordered to be constructed there.

THE official Norwegian paper just received contains the announcement that his Majesty the King of Norway and Sweden has been pleased to appoint Sir William Mitchell a Knight Commander of the Royal order of St. Olaf, in recognition of the services he has rendered to merchant shipping generally.

AT a meeting of the Liverpool Local Marine Board yesterday week, a telescope was presented to Mr. J. P. Anderson, late chief mate of the ship "Adept," in acknowledgment of his rescue of the crew of the water-logged ship, "Americana," in September, 1868. The captain of the "Adept" was ill at the time.

MESSRS. W. HAMILTON and Co. have launched from their yard at Port Glasgow a wooden paddle ship built for the Imperial Ottoman Government. The steamer, which has been named the "Amelia," is the fourth which Messrs. Hamilton have built for the Turkish Government, and a sister ship is now in course of construction in their yard.

THE United States War and Navy Departments have combined in the adoption of a uniform system

of signals to be used in the military and naval branches of service. Commander S. P. Lee, of the navy, and General Myer, of the army, will have charge of the respective branches, with the necessary corps of assistants. The work of reorganization is to begin at once.

A TERRIBLE accident occurred on Wednesday afternoon at Sheerness. One of H.M. gun vessels, the "Thistle," was undergoing some preliminary trials, when, from some cause at present unknown, a boiler burst, killing some seven men and seriously injuring fifteen others, several of whom are not expected to recover. After the catastrophe, the ship was brought to anchorage off the Mouse Light, her buoyancy being uninjured.

THE inhabitants of Deptford are taking action, through their respective vestries, for getting the abolished dockyard utilised, either as a metropolitan fish market in lieu of Billingsgate, or as a foreign cattle receiving and slaughtering yard and dead meat market. By the advice of Sir David Salomons, Bart., M.P. for the borough, a memorial has been drawn up, and is in course of signature, for presentation to the Lord Mayor, Aldermen, and Commonalty of the City of London.

SOME time since we described at length the four-rayed iron vessel of very light draught, which had been proposed by Captain Moody for a stable platform for floating forts and for floating telegraph and store stations. Determined to show the practical value of his system, the inventor has commenced building at his own cost a vessel 39ft. from ray to ray; and he intends to test in every way its asserted qualifications, as well as the capabilities of such craft under canvas and under steam. The builders are Messrs. Lewis and Stockwell, and it is expected the vessel will be finished in about six or eight weeks.

THE following contributions in aid of the funds of the Merchant Seamen's Orphan Asylum were received from the passengers, officers, and crews of merchant vessels, per favour of the captains, during the month of October:—"Lady Jocelyn," £10 10s. 1d.; "Rutlandshire," 2s.; "Pera," screw steamer, £2 5s. 11d.: "Sir Jamsetjee Family," £2 2s.; "Harkaway," 2s.; "Delhi," screw steamer, 7s. 10d.; "Nyanza," screw steamer, £1 11s. 6d.; "Simla," screw steamer, £4 12s.; "Taitsing," £1 6s. 10d.; "Fire Queen," £2 10s. 4d.; "Eliza Shaw," 4s. 4d.; "Syria," screw steamer, £22 4d.; "Tanjore," screw steamer, 4s. 4d; "Sumatra," screw steamer, £4 3s. 3d.; "Pride of the Ocean," £1 10s.; "Brinkburn," £2 3s. 9d.; "Cospatrick," £2 4s. 2d.

WE read that a new machine has been set to work at Naples, on a man-of-war, the "Calatifimi," which is called the Nausismografo. The inventor of this engine is M. F. E. Paroone, first machinist of the royal Italian navy. It is stated that, with the help of this machine, the damage which the ship has undergone can be found out, as well as the speed and the direction—in one word, all the different movements which a ship has been obliged to undergo, either on account of the winds or through any other reason. With this machine, the commander can from his cabin watch over all the movements of the ship. After a manœuvre or a battle, the manœuvreing of each ship can be found out. Finally, by this extraordinary machine, the journal of the commander is controlled on his return.

IT has come to our knowledge, and, for the sake of the naval service, we regret to add, with every evidence of truth, says the "United Service Gazette," that the command of one of her Majesty's ships on a distant station has been offered to a captain, provided he pays his own passage out to the station to join her! It has also been stated that the officer has accepted the command under the conditions stated, feeling that had he not done so he was likely to look in vain for employment. We most emphatically enter our protest against such a system. The national exchequer must indeed be low if it cannot afford to send an officer to the station on which he is to perform his duty. We hear it also currently reported that the tin mess utensils used in vessels conveying troops are to be purchased "second-hand!" Is the Board of Admiralty about to open an imperial second-hand establishment and naval commission agency? We see evident signs of attempting to conduct the affairs of the navy in a shop-keeping spirit. We warn the Admiralty and their financial secretary against such an attempt.

Miscellanea.

A MONUMENT to the Prussian statesman and patriot, Baron Von Stein, was opened at Herdeck on the 17th ult. It consists of a watch tower 90ft. high on the summit of the Kaisersberg.

THE remains of 6 men and 46 horses, supposed to be those of a missing portion of General Fremont's exploring expedition, 20 years ago, were found recently in the Opal Fork of the Rio Grande.

AT a meeting of the directors of the Edinburgh School of Arts, held on Monday, it was unanimously agreed to allow female students to attend the lectures and classes of the school.

A FINLAND vessel has just conveyed to St. Petersburg two enormous blocks of stone from the banks of Lake Ladoga, each weighing 72,000lb., to be used for the pedestal of the statue of Catherine II.

THE "Courrier du Gard" of the 23rd ult. says:—Yesterday, in the plains of Crau, the direct train from Marseilles was nearly thrown off the rails by the violence of the wind; two first-class carriages had part of their roofs carried away by a furious gust.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending October 30, was 3,605. Total number since the opening of the Museum, free daily (May 12, 1858), 1,674,621.

IT was stated by Sir James Simpson, when receiving the freedom of the City of Edinburgh, that among the manufactories of chloroform in Great Britain, a single one of these located in Edinburgh makes as many as 8,000 doses a day, or between 2,000,000 and 3,000,000 of doses every year.

WE regret to observe the continued indisposition of Mr. Bazalgette, the Chief Engineer to the Metropolitan Board of Works. It is satisfactory, however, to learn that the Board have granted him leave of absence for three months, during which time he will be relieved from all duties.

MESSRS. WEBB AND SON, of Coombs Tannery, near Stowmarket, whose leather bands were favourably noticed by us at the Agricultural Show at Manchester, met with well-merited success at the late Altona Exhibition, where they obtained the only medal given for leather machine bands over twenty-six other competitors.

COAL has been found by Government geologists near the salt works of Iletzkaya Zaschtschita, on the river Ilek, south of Orenburg, and in the peninsula of Mangushlak, on the eastern shores of the Caspian. It is reported to be of good quality, and will supply the steamers on the Caspian, hitherto fed with anthracite from the Don.

MESSRS. SIMPSON, engineers, of Thames Bank, are laying a thorough system of water supply at Buckingham Palace in case of fire. Four large iron cisterns have been placed at different points on the roofs, from which are laid pipes through the corridors and passages with hydrants and hose at intermediate distances, so as to be accessible to all parts of the palace in time of need.

THE number of visitors to the South Kensington Museum during the week ending October 30, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,559; Meyrick and other galleries, 1,502; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,654; Meyrick and other galleries, 88; total, 14,808. Average of corresponding week in former years, 10,711. Total from opening of Museum, 8,915,982.

IT is said that the North-Eastern Railway Company have determined to introduce at once a new improvement in the working of the points on their lines, viz., the wedge process, by which the pointsman, on closing his points with the ordinary handle from his cabin, will introduce a wedge into the points, and thus effectually lock them, and prevent them from jumping as the trains pass, and thus probably prevent accidents such as have more than once occurred.

DEATH, says the "Melbourne Argus," has at length removed from us the founder of the colony, the Hon. John Pascoe Fawkner, M.L.C., the man who, but a little more than thirty-four years ago, sailed up the River Yarra, and commenced a colony, the growth of which has been unexampled in history, and which, in all probability, will never be paralleled. At the age of seventy-six, respected by all who knew him, after a life eventful as a romance, and eminently active and useful, Mr. Fawkner has passed from us; but his name will be treasured as a household word long after the colony he founded has become an important empire.

THE Council of the Society of Arts offers its Silver Medal for the best instrument, to be affixed to a cab or other hackney carriage, for indicating the fare as between the passenger and the driver, whether by registering the distance travelled or otherwise, and which instrument shall also indicate for the convenience of the cab-owner and of the driver, the total distance travelled during the day, and the total amount earned. The instruments competing, with full descriptions of their construction, to be sent to the Society's house before January 1, 1870. Competitors may at their option sign their communications, or may forward with them sealed letters containing the name and address of the writer.

WE have much pleasure in calling attention to a well-arranged tool box which we recently examined at Messrs. Moseley and Son's Plane and Tool Manufactory, 54, Broad-street, Bloomsbury. This box, which is called the "householder's tool box," is of deal, dovetailed, and painted: it measures inside 26½in. long, 11in. wide, and 6in. deep, and is so arranged that any single tool can be got at readily, taken out and put in again, without disturbing the others. The tools comprise a very complete set of all that can be required for general purposes, and their quality is guaranteed by the maker's name, whilst the price is exceedingly moderate. A number of useful practical hints on the use of the various tools accompanies each box.

THE traffic receipts of the railways in the United Kingdom for the week ending October 24 amounted, on 13,569 miles, to £818,110, and for the corresponding week last year, on 13,414 miles, to £793,100, showing an increase of 155 miles and of £25,010 in the receipts. The gross receipts on the 14 principal lines in the United Kingdom amounted for the week, on 9,895 miles, to £684,576, and for the corresponding week last year, on 9,754 miles, to £667,087, showing an increase of 141 miles and of £17,479 in the receipts. The traffic receipts on 52 other lines in the United Kingdom amounted, on 3,674 miles, to £133,544, and for the corresponding week last year, on 3,660 miles, to £126,013, showing an increase of 14 miles, and of £7,531 in the receipts. The total receipts of the past week, as compared with those of the preceding one ended October 17, exhibit a decrease of £26,600.

UNITED STATES' papers publish a paragraph to the effect that the General Land-Office has received returns of the survey of the township and section lines of five townships on the Gila River in Southern Arizona, containing 105,252 acres of agricultural and grazing lands, bearing evidence of having been formerly under a high state of cultivation for centuries, and abounding in ruins of elaborate and sometimes magnificent structures, together with relics of extinct races possessing considerable knowledge of the arts and manufactures—among the most extensive of the ruins being those called Casa Grande, about two miles south-west of the junction of the east and south channels of the Gila River. These townships embrace the growing towns of Adamsville and Florence, on the Fort Yuma and Fort Grant waggon roads, as well as numerous productive farms and pastures well stocked with cattle and sheep.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1075, 1079, 1085, 8104, 1110 1128, 1129, 1134, 1137, 1155

BUILDINGS AND BUILDING MATERIALS—1130, 1153, 1158, 1164

CHEMISTRY AND PHOTOGRAPHY—1147, 1152

CULTIVATION OF THE SOIL, including agricultural implements and machines—1078, 1083, 1103, 1133, 1161, 1174

ELECTRICAL APPARATUS—1076, 1136

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1094, 1095, 1099, 1113, 1145

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1083, 1112, 1121

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1082, 1084, 1090, 1096, 1105, 1108, 1122, 1131, 1141, 1154, 1163, 1165, 1170, 1176

GENERAL MACHINERY—1080, 1087, 1088, 1091, 1119, 1135 1142, 1159, 1160, 1167, 1169

LIGHTING, HEATING, AND VENTILATING—1077, 1102, 1111, 1147

METALS, including apparatus for their manufacture—1100, 1107, 1144, 1149

MISCELLANEOUS—1081, 1089, 1098, 1101, 1106, 1114, 1124, 1138, 1139, 1157, 1168, 1175

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1074, 1086, 1092, 1115, 1116, 1117, 1118, 1120, 1123, 1125, 1126, 1146, 1148, 1156, 1162, 1172

SHIPS AND BOATS, including their fittings—1104

STEAM ENGINES—1097, 1140, 1150, 1151, 1166, 1171

WARFARE—1093, 1127, 1143

1074 W. T. O. PRATT, Newport, Monmouthshire. *Signalling apparatus.* Dated April 8, 1869.

This consists of rods and levers leading from the whistle or other sound-creating instrument on the engine or in connection with it, within the hearing of the driver, and a wire, cord, or other appliance which is screwed or otherwise acted upon by coming in contact with a blade, bar, or lever placed above the rail or rails or in the space between the rails. The blade, bar, or lever is thrown or put into position at a distance by an attendant or by a lever on the rod of the danger signal and worked in conjunction therewith. Weights and springs may be employed in connection with the apparatus to ensure its proper working.—Patent abandoned.

1075 G. D. HUGHES and A. H. SELLERS, Nottingham. *Safety valves.* Dated April 9, 1869.

The inventors make and attach to the boiler, externally or internally, an apparatus consisting of a casting forming a box, chamber, or hollow vessel, containing one or more valves, one of which valves they propose to make of a spherical, conical, or other suitable form, to be fitted into and supported upon a seating of similar form perfectly steam-tight when down upon the face. To this valve they attach a dead weight by means of a rod fixed to the centre of the valve, such dead weight to be so arranged that it will balance the pressure of steam upon the under surface of the valve to the pressure per square inch at which the boiler may safely be worked, or at any other lower pressure that may be required.—Patent completed.

1076 J. ASPINALL, Harrow. *Telegraph cables.* Dated April 9, 1869.

This refers to letters patent granted to C. F. Varley, dated 29th August, 1868 (No. 2,683). The invention consists in serving the ropes or cable as it comes from the spinning machine with a serving of yarn laid on in the opposite direction and with a shorter lay than that of the two strands or ropes and insulated conductor. A further improvement consists in worming the cable with a worming of yarn more elastic than the material of which the strands are composed. These wormings afford support and protection to the insulator, and make a rounder and better cable for manipulation, besides adding strength.—Patent completed.

1077 W. A. HUNTER, Southport. *Lighting street lamps.* Dated April 9, 1869.

This consists in a tube fixed upright or at an angle if required, containing a quantity of matches, and with a swivel plate, into a recess in which the lowest match in the tube drops. This swivel plate is turned partly round by a rack and pinion or other equivalent, and in turning round the match is rubbed against a rough or prepared surface to ignite the match and to bring it near to the burner. The rack or other equivalent for moving the swivel plate is connected to a rod, which is raised by water or other fluid or other power, and this rod, which is carried up inside the lamp-post, is connected by a link to the tap, which turns on or off the gas in such a manner that when the rod is raised the tap is opened, and the gas escaping from the burner comes in contact with and is ignited by the burning match.—Patent completed.

1078 T. CULPIN, Reading. *Reaping and mowing machine.* Dated April 9, 1869.

The beam is formed into a flat tube or hollow bar made of sheet steel or other metal, thereby forming a trussed beam, thus giving greater rigidity thereto with a given quantity of material.—Patent abandoned.

1079 J. A. MILLER, New York, U.S.A. *Steam boilers.* Dated April 9, 1869.

The inventor constructs steam boilers with a number of units or chambers in the form of hollow slabs having flat sides and cylindrical tops and bottoms. The sides of these hollow slabs are held together by tubes either expanded into holes made in the sides of the hollow slabs or secured in them by ferrules, or by welding or otherwise, and the ends of these hollow slabs are closed by plates. Any suitable number of these hollow slabs are set side by side, and both the water and the steam space of each of the hollow slabs is connected with the other. The frame and heat from the furnace is caused to pass round and between the hollow slab, as well as through the short tubes connecting their flat sides. By this means a large heating surface is obtained in a small space, and combustion is more complete, the gases from the furnace being continually mixed.—Patent completed.

1080 J. DENIS, Rue St. Louis, Paris. *Conical cog cutting.* Dated April 9, 1869.

This improved machine fits on to all kinds of lathes without changing their system, all that is necessary being to make the face plate of the lathe to divide at its upper part, and to fit it with a movable index to indicate the required division. The cog-wheel to be divided being turned without displacing it from above the lathe, it is fixed to the face plate, so that it follows all the movements of the latter. The tool which has served to turn the toothing is then removed from the slide; the tool holder is substituted in a vertical position with the tool, which exactly forms the space intended to be left between the cogs placed in the mortice of the vertical shaft of the cutting machine. The index being on the desired division, the band is passed over the shaft pulley to give motion to the shaft, which should make from 2,800 to 3,000 revolutions a minute. The tool is advanced so as to make the tooth at a single pass or traverse. Being on the required division, the tool is made to travel parallelly to the toothing by means of the slide crank. Directly the pass is made, the face plate is turned (as also the cog-wheel to be cut, it being fixed to the face plate) until the desired point is facing the index, and the tool is brought back, making its pass quite as easily as in advancing. In many cases, to shorten the work, the slide screw may be removed, and the tool run by hand.—Patent completed.

1081 R. J. MORISON, Mark-lane, E.C. *Bale presses.* Dated April 9, 1869.

The base of the machine forms the bottom plate of the press, and may be placed or erected either upon the ground or upon a suitable frame. This plate has its upper surface slotted in the usual manner to receive the binding ropes, when the material compressed is to be covered or enclosed. Upon the base plate or upon the ground frame are fixed (one on each side) two vertical guide bars properly bound by means of tie bars. When the press is large two pairs of guide bars may in some cases be found advantageous.—Patent completed.

1082 R. J. COLLS and A. E. BULL, Reading. *Fastenings for boots.* Dated April 9, 1869.

The two edges of the upper which are to be secured or united for the purpose of fastening the boot are each provided with a bead or rounded edge, formed, preferably, by turning the edge of the leather over a gut or other cord. The two beaded edges are held together by a number of X-shaped fastenings of metal or other material, attached at convenient distances apart to a flexible strip prolonged at one or both ends to form a tab, by which the row of fastenings may be slid on or off the beaded edges before mentioned, for the purpose of securing or unfastening the boot, as the case may be.—Patent abandoned.

1083 J. DEWAR, Kirkcaldy. *Food and manure.* Dated April 9, 1869.

The inventor takes dreg and evaporates it by exposing it to the action of heat applied directly or through the medium of hot air until he obtains the residuum therefrom in a dry state. This residuum may be used either broken into pieces or reduced to meal or powder, and may be given for food either alone or mixed with other vegetable matters, and when so treated and used it is found to form a very nutritious article of food.—Patent completed.

1084 C. J. F. CAMPBELL, Camberwell. *Hanging pictures.* Dated April 9, 1869.

To the back of the picture or looking glass frame a metal plate is screwed, which has a projecting tongue with a hole or eye in it. A staple is driven into the wall, and has a circular peg cast on and forming part of it, and fitting the hole or eye in the tongue piece. When the picture is to be hung, the hole in the projecting tongue of the metal plate is passed over the circular peg on the staple.—Patent abandoned.

1085 C. LUNGLEY, Greenwich. *Removing deposit from flues.* Dated April 9, 1869.

This apparatus consists of a pipe to be worked to and fro in the tubes, flues, or passages, by hand or mechanical means. The pipe is supplied with steam, air, or liquid under pressure from a generator or reservoir. The action of the steam, air, or liquid against the soot or deposit in tube or passage causes it to fall away from the sides, and the force of the current drives it out of the tubes or flues. Sometimes the inventor fits a cap over the end of the pipe, and in this case he perforates the pipes with holes either straight or diagonally in any direction, or he perforates the cap, through the holes or perforations in which the steam, air, or liquid is caused to pass and impinge against soot or deposit for the same purpose.—Patent completed.

1086 W. W. HOOPER, Bow, and J. D. HOOPER, Woodford. *Vehicles.* Dated April 9, 1869.

The inventors connect a lever with the axle of the driving wheel or to a wheel so placed that it may be connected with the driving wheel to multiply its revolutions. The lever is made to act on the wheel with which it is connected by means of a pawl furnished with or without lugs, projections, or claws, which are caused to impinge against or grip a flange or ring on the wheel, axle, or spindle, in one course of their stroke, and to escape or be released on their return stroke. Springs are employed in connection with the levers and pawls to ensure their proper working.—Patent completed.

1087 W. E. NEWTON, Chancery-lane. *Obtaining motive power.* (A communication.) Dated April 9, 1869.

The object of this invention is to dispense with the treadle and crank usually employed for driving light machinery, such, for instance, as sewing machines. In such an instance, the sewing machine is secured as usual on an elevated table, and this is mounted on the upper end of a vibrating lever frame, which is capable of rocking on centres below, and is connected with a system of parallel levers, which are also capable of rocking on centres. The seat of the operator is placed on the rocking levers, so that the whole machine may be vibrated or rocked to and fro like an ordinary rocking chair. The sewing machine is worked by the force of a coiled spring contained in a barrel, which is placed under the table, and is connected to the sewing machine above by suitable gearing as in ordinary machines which are actuated by a treadle.—Patent abandoned.

1088 A. V. NEWTON, Chancery-lane. *Rotary engines and pumps.* (A communication.) Dated April 9, 1869.

This relates to engines or motors formed of two cylinders, one within and eccentric to the other, and provided with sliding pistons having a radial relationship to the inner cylinder, and working within and against the outer one, which is stationary, while the inner eccentric revolves with the pistons. The invention consists in the combination with those parts of one or more loose rings arranged within the inner cylinder and clipped by the inner ends or portions of the sliding pistons, which are thus connected in a free and independent manner to work in unison with each other and in close but free contact with the stationary outer cylinder, the loose ring or rings being kept concentric with the outer cylinder by means of the pistons, and the latter being kept in contact with the outer cylinder by means of the ring or rings. This combination and arrangement of the parts admits of the main shaft, which is connected with the inner cylinder and concentric thereto, being extended if desired through both cylinders.—Patent completed.

1089 T. H. BLAMIRES, Huddersfield. *Vote receiver and indicator.* Dated April 9, 1869.

According to this invention votes are received and registered by means of movable indexes such as are now used for counting the strokes made by the piston of a steam engine or in gas meters for registering the quantity of gas passed through, or by other similar indicating apparatus, which is actuated by the voter by means of levers either by his hand or foot or by a turnstile. The apparatus is carefully arranged, so that the voter can only give the correct number of votes.—Patent abandoned.

1090 W. R. LAKE, Southampton-buildings, Chancery-lane. *Waterproofing fabrics.* (A communication.) Dated April 9, 1869.

The inventor prepares a solution of paraffin by dissolving paraffin in pure naphtha, that is to say, naphtha free from any oily or greasy matter, or which will not stain letter paper when dipped into it and dried. The paraffin should be cut into small pieces and put into the naphtha in an easily and tightly closed vessel, and should then be well shaken or agitated. In this way a saturated cold solution may be quickly obtained without the use of heat. It is best to use an excess of paraffin in the naphtha, so as to have a saturated solution at about 70deg. of Fah. Into this solution the fabric is to be immersed.—Patent completed.

1091 P. JENSEN, Chiswell-street, Finsbury. *Pumps and syphons.* (A communication.) Dated April 9, 1869.

This consists in application of a jet of steam for the purpose of exhausting the air contained or accumulating in syphons, and in the bodies and pipes of centrifugal or other pumps.—Patent completed.

1092 H. W. LOBB, Sackville-street. *Velocipedes.* Dated April 10, 1869.

This velocipede is constructed with two wheels of large diameter formed of iron, or iron in combination with other material, and connected by a transverse axle, on the ends of which the wheels are respectively mounted so as to be free to revolve. The axle is bent in a backward direction somewhat in the form of a double crank. A bar of T-iron passes through or is attached vertically to the centre of the axle; this bar is curved, and the upper part provided with a wooden back furnished with a suitable padding for the support of the shoulders of the velocipedist.—Patent abandoned.

1093 S. F. VAN CHOATE, Boston. *Firearms.* Dated April 10, 1869.

In this arm the breech frame may be made integral with the barrel, although it is preferred to make it separate from the barrel, which is then screwed into the front end of the breech frame. From the end of the barrel, which is properly bored to receive flanged metallic cartridge sheets, the breech frame is slotted to its rear, the slot opening at the top of the frame and having straight parallel vertical sides and a concave bottom concentric with the axis of the barrel. At the rear of the frame the bottom of the slot is formed with a large radius to receive the recoil block or cam by which the breech-piece is locked and unlocked, the breech-piece being of such shape as to fill the slot in the breech frame.—Patent completed.

1094 E. BRASIER, New Cross, and J. E. HODGKIN, West Derby. *Flax cleaning.* Dated April 10, 1869.

In place of fixing wooden blades to iron or wooden radial arms to form the scutching blades of a radial scutching wheel, the inventors form such scutching blades in one piece of wood. By means of bolts they secure the improved scutching blades to a central boss, which they prefer to form of cast iron or other metal. The bosses are secured upon the axis, which revolves in bearings formed in suitable supports.—Patent completed.

1095 W. SMITH, Heywood, Lancashire. *Looms.* Dated April 10, 1869.

This consists in the application of a counter-acting tappet acting on the spring of the lever for putting in the wires.—Patent abandoned.

1096 H. A. BONNEVILLE, Sackville-street, W. *Sewing machines.* (A communication.) Dated April 10, 1869.

This consists, first, in making the needle bar and the presser slide either or both in the form of tubes closed below so as to prevent the oil used in lubricating the same from falling on the table and spoiling the work. Second, in the combination of a common holding plate or screw with the guide rods of the tubular needle bar and the tubular presser slide in such a manner that the operation of fastening the guide rods in position is materially facilitated; and, third, in making the guide rods of the tubular needle bar and of the tubular presser slide hollow, so that the air is allowed to pass in and out of the slides during their descent and ascent on the guide rods, and so that room is obtained for adjusting and operating various attachments for making different seams and fancy stitches.—Patent completed.

1097 W. ASHTON and J. H. STOREY, Manchester. *Ascertaining duty of steam engines.* Dated April 10, 1869.

A comparatively small cylinder is fitted with a piston, and is connected with the cylinder of the steam engine in such a manner as to allow the piston to be acted upon by the pressure of the steam or by the force due to the continued action of steam and of a partial vacuum at the same times and to the same degree in proportion to its area as the piston of the steam engine. The piston rod of the indicator is connected with a spiral spring, which controls the action of the indicator piston, the said spring resisting the movement of the said piston in either direction from the position of equilibrium, which is at about the centre of the cylinder, the spring being made about proportionate to the area of the piston and to the pressure acting thereon. On the piston rod is mounted a friction wheel or pinion, to which a variable rotary motion is imparted during the working of the engine by a disc, the surface of which is in contact with the circumference of the said friction wheel. The disc is caused to rotate alternately in opposite directions, the rotation being derived from the engine similarly as in the case of the barrel of the ordinary indicator, or in any suitable manner, the disc rotating to a suitable extent in one direction during the forward or upward stroke of the piston of the engine, and in the reverse direction during the return stroke thereof.—Patent completed.

1098 J. HYNAM, Deptford. *Crucibles.* Dated April 10, 1869.

This relates to means of gradually altering the position of the crucible relatively to that of the shaping tool while the crucible is being shaped, and of regulating or adjusting the apparatus to make crucibles of various sizes. For this purpose the inventor connects the revolving table or lathe which carries the mould frame and moulds to a lower frame, which is pivoted or hinged at one end, and is free to be moved in the arc of a circle like a wicket or gate. Adjustable stops regulate the distance to which this frame can be moved. The plastic material having been put in the mould, the tool placed therein, and rotary motion imparted to the revolving table and mould, the lower frame is gradually moved on its pivot with the revolving table and mould so as to bring the circumference of the mould gradually nearer the tool until the desired position is reached, which position is regulated by the adjustable stop according to the required size of the crucible.—Patent completed.

1099 J. M. HETHERINGTON, Manchester. *Combing cotton.* Dated April 10, 1869.

This consists in causing the backward motion of the rollers which convey the tufts to exceed one half of their forward movement.—Patent completed.

1100 J. B. SPENCE, Manchester. *Treating cast iron.* Dated April 10, 1869.

This consists in a method of using the salts whereby the decomposition is, to a certain extent, retarded. For

this purpose, the nitrate of soda or other salt is brought into a more or less solid body before the melted iron is allowed access to it.—Patent completed.

1101 P. HEADRIDGE, Lime Grove, Manchester. *Dentistry.* Dated April 10, 1869.

The upper and lower maxillary is expanded by a sectional base or plate. This sectional base or plate can be made of vulcanite, gold, or other materials. These sections are united by a spring or springs. The upper maxillary is expanded by means of a sectional base or plate covering the palate and back teeth. This sectional base or plate meets on the median line of the maxillary. Situated interiorally are two shoulders on the base near to the grinding surface of the teeth on each side to receive and hold a spring that fits close to the base. When put in the mouth, the spring exerts pressure against the sides, causing the upper maxillary to open in the centre, at the same time opening the nasal cavities.—Patent completed.

1102 D. B. PEEBLES, Edinburgh. *Gas meters.* Dated April 10, 1869.

This consists, first, in uniting the parts of gas meter castings of sheet iron by means of grooves and tongue joints. Second, in making the snugs for the fastening screws with guard flanges. And third, in applying a separate cover with details in connection with it over the crank spindle of a dry meter.—Patent completed.

1103 E. C. C. STANFORD, Glasgow. *Deodorising sewage.* Dated April 10, 1869.

The inventor employs instead of earth some kind of charcoal. He prefers seaweed charcoal on account of its high absorptive power and its cheapness, but any other charcoal may be used. Of this material only one-fourth the quantity as compared with earth is required. He finds 12cwt. of charcoal per annum to be sufficient for each closet when used by six persons, so that the total quantity to be removed does not exceed the house ashes. The mixed product from the closets is perfectly black and inodorous, so that it can be allowed to fall at once from the closet through a 12in. drain pipe directly into a small watertight cesspit built of brick and cement in the basement of the house, from whence it need be removed only once a year. One cartload or 24cwt. per annum is the produce of each closet. The charcoal to be used in the closets is in a granular form and is used in the same way as the earth in the ordinary dry closet, and with the aid of the same or similar appliances or apparatus. —Patent completed.

1104 G. HAWORTH, H. HAUGHTON, and R. GIBBONS, Blackburn. *Consuming smoke.* Dated April 10, 1869.

The inventors construct the bridge with an elongated opening therein. This opening is covered by a damper plate, to which is attached a rod supported by a crossbar at each end thereof, which extends from the damper plate to near the front of the flue. To the front end of the rod is attached an arm so constructed that, on the furnace door being opened, the damper plate is drawn from the opening in the bridge, and admits the cold air to the flue by way of such opening instead of direct to the fire during the operation of firing.—Patent abandoned.

1105 O. VIVIER, Sekforde-street, E.C. *Escapement for watches.* Dated April 10, 1869.

Instead of employing a large number of teeth and pins in the scape wheel (fifteen) as heretofore, the inventor forms such scape wheel with five or a less number of teeth (three by preference), and with a similar number of pins to give the impulse to the finger on the axis of the balance wheel, such finger being considerably larger in proportion to the scape wheel than has hitherto been the case. This arrangement requires an intermediate wheel connected with the scape wheel.—Patent completed.

1106 J. H. JOHNSON, Lincoln's Inn-fields. *Removing hair from skins.* (A communication.) Dated April 10, 1869.

This consists essentially in the employment of thin flexible straight blades, which are sprung into helicoidal grooves or seats made in the surface of the carrying drum or cylinder, and which are held in position by means of bolts and counter plates.—Patent abandoned.

1107 J. PARRY and R. MORRIS, Llanberis, Carnarvonshire. *Saws for metal.* Dated April 10, 1869.

This improved saw consists of three separate plates of iron forming the saw disc, riveted or otherwise fixed together. In the middle of these plates grooves are cut for the purpose of fixing in the steel cutters, which are held tight in their proper position by springs attached to the side of the saw or by other means.—Patent completed.

1108 E. T. HUGHES, Chancery-lane. *Improved stitch.* (A communication.) Dated April 10, 1869.

This consists in passing the needle and its thread through the under layer or thickness, partially through the upper layer or thickness, and out through the under layer or thickness, forming a stitch either by a chain made from the needle thread or by the interlacing of a second thread.—Patent completed.

1109 W. MARTIN, Manchester. *Shipbuilding.* Dated April 10, 1869.

The inventor forms the body of the ship or vessel of two parts or shells, both watertight at the bottom and sides, and fits the upper part into the lower one, and afterwards fixes the parts together by clamps, bolts, wedges, or by any of the well-known means of keeping large bodies together. The lower part holds the ballast engine and boilers, the fuel, and the bulk of the heavy merchandise; and, in the upper part, the cabins of the passengers and compartments for the mails, specie, and the more valuable part of the cargo are formed.—Patent abandoned.

1110 L. J. CROSSLEY and R. HANSON, Halifax. *Steam and air valves.* Dated April 10, 1869.

To an ordinary equilibrium valve the inventors preferably apply a cylindrical or other formed chamber, through which the valve rod passes. This chamber is constructed so as to form an annular reservoir for containing a column of mercury of suitable height, according to the amount of reduction required to be made in the pressure of the fluid to be discharged.—Patent abandoned.

1111 J. WADSWORTH, Manchester. *Lighting fires and economising fuel.* Dated April 10, 1869.

This consists in constructing an open-ended sheet or cast iron casing of any suitable shape having holes formed near its lower end, through which a portion of the clips used for lighting the fire are passed, so as to form a grid or support for other clips or other igniting materials, upon which the coals are placed, such coals being used by preference in small pieces. The inventor also forms other holes or slots in the casing for the admission of air.—Patent completed.

1112 D. JOHNSON, Wrexham. *Manufacturing flour.* Dated April 10, 1869.

This consists, first, in cutting the grain into thin slices or small pieces before reducing it to flour. Second, in the peculiar arrangement of a series of rotating knives or blades within a drum or case, which knives divide the grain into thin slices as they fall through a hopper. Third, in the peculiar arrangement of a series of reciprocating knives working above a horizontal disc, whereon the wheat or other grain is fed by a suitable hopper, this disc carrying the grain under the knives, which chop it into small pieces. Fourth, in the arrangement of rollers to work with their peripheries moving together to reduce the wheat or other grain, or portions of wheat or other grain, to flour, one of the rollers being made to run quicker than the other.—Patent completed.

1113 J. H. DALES and J. F. MAYGROVE, Wood-street E.C. *Looms.* Dated April 10, 1869.

A warp thread is passed between each of the dents of the reed, entirely across the same, in the usual manner. Below this warp foundation the inventors place a second row of warp threads, about forty or fifty in number, more or less arranged in two sets of equal number, one on either side of the centre of the piece. These two sets of threads constitute a second warp or warps, through which and through the opposite half of the upper warp, the weft threads are caused to pass alternately, the other half of the upper warp being raised clear of the shuttle until the next stroke by the jacquard or other suitable apparatus.—Patent completed.

1114 A. M. CLARK, Chancery lane. *Fountain pens.* (A communication.) Dated April 10, 1869.

The ink is contained in a tube of india-rubber or other elastic or flexible material. This tube is filled by doubling and squeezing it together so as to eject the air, the ink in which it is dipped being at once taken up by reason of the vacuum thus produced. This ink tube is enclosed in the case which constitutes the penholder.—Patent abandoned.

1115 W. CROMBLEHOLME, Manchester. *Automatic registrar.* Dated April 12, 1869.

This automatic registrar, which is described as applied to omnibuses, consists of two dials with registering fingers, the one for inside and the other for outside passengers. Each dial has one or more index fingers, which are actuated by a footboard, placed in the floor of the omnibus or on the steps. The footboard is connected by links and levers to a catch acting on a ratchet wheel, and this ratchet wheel is moved one tooth by every passenger entering into and going out of the omnibus. A second ratchet wheel is placed near the first, but having teeth in the opposite direction. This second ratchet wheel has a retaining catch and toothed break, and is to prevent the first one moving more than one tooth at a time.—Patent abandoned.

1116 E. D. TEMPLE, King William-street. *Railway signals.* Dated April 12, 1869.

This consists, first, in constructing railway semaphore signals of wrought-iron tubes of convenient lengths, bent or otherwise, and suitably connected by wrought or cast iron connecting joints and bearing plates. Second, in tying the tubes firmly together by means of one or more wire or other ropes, which may be fixed externally to the tubes or passed through the tubes themselves and subjected to any required degree of tension by means of a small wheel and ratchet or other suitable apparatus worked by a lever or otherwise, by which any lateral weakness of the signal is effectually counteracted. Third, in employing the arms of the semaphore signals for indicating the names of adjacent stations or giving any similar short notice of a permanent kind.—Patent abandoned.

1117 J. KIRK, Woolwich. *Cabs and carriages.* Dated April 12, 1869.

This consists in enclosing the footboard with side doors and front rails to receive the sides and front of the hood, which shuts down upon them.—Patent completed.

1118 S. F. SHORE, Uttoxeter. *Moving railway carriages.* Dated April 12, 1869.

This relates to an arrangement by which railway carriages may be moved short distances without the use of animal power, and the invention consists in attaching to each carriage a toothed wheel provided with a handle or crank, such wheel taking into a pinion on a shaft which works in suitable bearings beneath the carriage. This shaft is provided with a worm or screw gearing with a toothed wheel usually horizontal which gears with another toothed wheel on the axle of two of the wheels of the carriage, truck, or vehicle.—Patent abandoned.

1119 J. EASTON, Taunton. *Drop drills.* (A communication.) Dated April 12, 1869.

These drills are preferably made in three parts, the middle part being an oval casting forming a double bearing for the lever, and terminating in two sockets at opposite ends thereof to receive two prolongations which are held in place by keys.—Patent completed.

1120 W. R. LAKE, Southampton-buildings. *New railway.* (A communication.) Dated April 12, 1869.

The way consists of a line of vertical columns or pillars, which may be constructed of iron, stone, or wood. The columns project above the ground upon which they are erected from five to eight feet, and are placed at intervals of from eight to ten feet or more. The columns are connected by rails fastened therein at different heights. The main or vertical rail passes along the tops of the columns, and is designed to support the entire load of the train; this main rail is constructed of two single rails connected together, while the supplementary rails for preserving the balance of the carriages and for other purposes, are placed beneath the minor rail.—Patent abandoned.

1121 E. BEANS, Cordwalles. *Brewing.* Dated April 12, 1869.

This consists in the application and use of neutral or monosulphites of calcium, magnesium, aluminium, and ammonium, such as malt or sugar, or they may be mixed with the water added to them, either before their entrance into the mash tun, during the process of mashing, or during the process of boiling the wort with the hops, but, by preference, the inventor operates with them during the washing process.—Patent completed.

1122 A. D'AZAMBUJA, Joinville-le-Pont, France. *Felted fabrics.* Dated April 12, 1869.

On a table or like surface the inventor places a piece of canvas, and spreads hair cloth thereon, over which he extends one or more layers of animal hair, and thereon he places another layer of hair cloth, and he then spreads over all a second piece of canvas. He sews or otherwise attaches the two pieces of hair cloth together at all their edges, so that the layers of animal hair are enclosed therein.—Patent completed.

1123 H. BROWNE, Liverpool. *Velocipedes.* Dated April 13, 1869.

The front or driving wheel is made in the ordinary manner, having a fixed axle or spindle in the nave. This axle or spindle works in a bush of the following description:—This bush is made, by preference, of brass (but may be made of other metal), and is formed of a cylindrical piece, having collars projecting at both ends on the outside. Inside the cylinders or bush there is a small flange or projection at the side nearest the crank, and working into this cylinder there are a series of rollers which are fitted to work into two washers, one on the outside nearest the crank, and one on the inside or side nearest the nave.—Patent abandoned.

1124 C. D. ABEL, Southampton-buildings. *Aerial navigation.* (A communication.) Dated April 13, 1869.

This consists in constructing a narrow platform, to each side of which are hinged wings of a form approximating to a quadrant of a circle, constructed of a light but strong framing of wood, the surface inside which is filled in with thin louvre boards, laths, or staves.—Patent abandoned.

1125 S. HOLMAN, Laurence Pountney-lane. *Velocipedes.* Dated April 13, 1869.

The front wheel is provided with an axle, which may be either fixed in the boss or nave of the wheel, or be so made that the wheel will rotate without the axle revolving.—Patent abandoned.

1126 T. F. CASHIN, Gresham House, E.C. *Railway signals.* Dated April 13, 1869.

To the standard of the switch lever for which letters patent (No. 3,128) were granted to the same inventor the 13th of October, 1868, he now proposes to attach an upright rod or pipe mounted on a pivot, and passing through a bracket or arm projecting from the standard at any required height. At the top of this rod a lamp with two discs is fixed, and a light with a plummet dropped inside the pipe, so that the lamp may turn without the light necessarily turning.—Patent abandoned.

1127 T. B. BURNS, Camelford. *Cases for breech-loaders.* Dated April 13, 1869.

The inventor forms that portion of the case for containing the ammunition of a very thin case or shell of metal, by preference, of or about the 32nd part of an inch in thickness. By this means, the case when inserted in the breech piece of the firearm imperceptibly decreases the size of the breech end of the bore. The ammunition can be readily introduced from the muzzle if desired, or when the case is loaded in the hand, the charge when inserted in the breech as nearly as may be fills up the bore.—Patent abandoned.

1128 W. BROCK, Glasgow. *Slide valves.* Dated April 13, 1869.

This consists mainly in a peculiar form of slide valve in combination with another valve or plate, and so arranged that a very large area for steam admission is obtained with a very short travel of valve, whilst the plate is also made to answer the purpose amongst others of a supplementary or starting valve, with the additional advantage that the attendant cannot through carelessness blow steam through into the exhaust pipe, as with the ordinary arrangement of starting valves.—Patent completed.

1129 J. ROBERTS, Birmingham. *Fire draw plates.* Dated April 13, 1869.

The inventor makes the draw plate of a sheet of metal of a breadth somewhat greater than the length of the firebars and of a length about double its breadth. He bends this plate near its middle to nearly a right angle, and also bends it near its end to nearly a right angle, the bending in the latter case, being in a different direction to that in the former. The plate of metal thus bent constitutes a draw plate, which, when placed upon an ordinary oven grate, completely covers the top of the fireplace, the chimney hole, and the upper part of the firebars.—Patent abandoned.

1130 C. TURNER, Southampton. *Cowls for chimneys.* Dated April 13, 1869.

The inventor mounts a cowl (preferably bell-shaped) so as to oscillate on a central pivot fixed inside the top of the cowl. This pivot is tapered to a point, which is received in a conical socket placed above the centre of the chimney in suitable supports. The cowl in this manner is so nicely balanced that the slightest breeze will incline the windward side of the cowl against the chimney top, and prevent all down draught at the same time that the smoke is free to escape at the opposite direction.—Patent completed.

1131 B. J. B. MILLS, Southampton-buildings. *Boots and shoes.* (A communication.) Dated April 13, 1869.

In the machinery for the manufacture of boots and shoes, according to the inventor, the looping and feeding mechanism and the cast-off (which is employed to prevent the hooked needle from catching the same loop a second time) may all be constructed and arranged in any manner which is usual in machines of the same class in which a waxed thread is used and a chain stitch made, or in any other proper way. For manufacturing simple turned shoes without welts, the upper leather and sole are applied inside out to a last, which is preferably chamfered or grooved around the margin of its bottom to afford room for the hooked end of a bar, which, extending around the edge of the sole, bears against that face thereof which is next the last, and serves in conjunction with a vibrating bar, whose end bears against the outer face of the sole or against the upper leather over the sole, to clamp the sole firmly near its edge for the purpose of holding it in proper position horizontally, and, in some classes of work, to bend the sole at the time and place of stitching in such a manner that a straight needle may be made to dip into the sole and pass out on the same side or surface at which it enters, and then through the upper leather without passing through the entire thickness of the sole.—Patent completed.

1132 R. E. and C. MARSHALL, Cheltenham. *Distributing fumigating matter.* Dated April 13, 1869.

The apparatus consists of a frame mounted upon wheels. One of the wheels is adjustable on the axle for the purpose hereafter explained. This wheel can be put in com-

munication with a toothed wheel on the axle, which wheel is made to gear with a pinion on a shaft or spindle supported in bearings attached to the frame. This spindle also carries a band wheel, over which a band is passed. The band leads to a pulley or band wheel on the axle of a fan or blower fitted inside a casing attached to the frame. The frame is surmounted by a vessel, into which tobacco or other fumigating medium is placed. The lower part of this vessel leads by means of a tube to the fan or blower. —Patent completed.

1133 W. GILLESPIE, Coupland-terrace, Plumstead. *Furnace bars.* Dated April 13, 1869.

This consists in causing the firebars to rotate on their respective axes all in one direction simultaneously for the purpose of breaking up or disturbing the fuel thereon, and conducting it gradually from the mouth or entrance by which it is fed into the furnace so that the green fuel shall be carried towards the bridge of the furnace, at which part, the fuel being in a highly incandescent state, the gases evolved from the green fuel near the mouth of the furnace as they pass over the incandescent portion of the fire shall be consumed, and smoke prevented or very considerably lessened, and fuel economised.—Patent completed.

1134 W. E. NEWTON, Chancery-lane. *Railroad joints.* (A communication.) Dated April 13, 1869.

This consists in connecting the ends of the rails by a tongue and groove, and by a stay and side rail for breaking the joint, and to assist in resisting the tread of the wheels.—Patent completed.

1135 A. V. NEWTON, Chancery-lane. *Fan blower.* (A communication.) Dated April 13, 1869.

This consists in arranging a series of diaphragms within a number of cases or shells, in which a series of fans attached to a rotating shaft are provided.—Patent completed.

1136 J. H. JOHNSON, Lincoln's Inn-fields. *Manufacture of telegraph wire.* (A communication.) Dated April 13, 1869.

The various parts of the machine are so arranged and operated as that the sheathing, originally in the form of a flat ribbon, shall be first bent longitudinally into the form of a trough by passing between a pair of revolving die wheels made with concave and convex edges respectively. These wheels revolve not only on their own axis, but round the wire to be sheathed, which passes along in company with the sheathing through a hollow revolving shaft carrying a face plate and pair of jaws, one of such jaws being grooved for the passage of the trough-shaped sheathing and wire enclosed therein.—Patent completed.

1137 F. ERSKINE, Manchester. *Firebars.* Dated April 13, 1869.

This consists in forming the firebars with a vertical projection from that end of the firebar nearest the firebridge of such height as to come to a level with the top of the firebridge. These vertical projections are made so that there will be open vertical spaces between them from the under side of the firebar to the top of the projections, through which air can ascend and get heated, and, in its progress, meet the products of combustion at the firebridge.—Patent completed.

1138 J. H. JOHNSON, Lincoln's Inn-fields. *Dental wash.* (A communication.) Dated April 13, 1869.

The composition of this wash is as follows:—Essential oil of badiane or star aniseed, by measure, 2,000 parts; ditto French peppermint, 1,800 parts; ditto English peppermint, 0·350 parts; ditto of roses, 0·125 parts; ditto of cloves, 0·125 parts; alcohol of 40deg. of strength, 15·000 parts; ditto 53deg. of strength, 119,000 parts. The essential oils are to be mixed together, and the mixture is then to be added to the proportion of alcohol above mentioned. The desired tint may be imparted to the mixture by the aid of cochineal, and the whole is to be filtered, after which it will be ready for use.—Patent completed.

1139 M. SAMUELSON and C. ESKRETT, Kingston-on-Hull. *Expressing oil.* Dated April 13, 1869.

The inventors employ a metallic envelope composed of two separate corrugated plates of wrought iron, copper, or other ductile metal, backed by a wrought-iron frame and plate. The upper plate of the envelope is firmly fitted into and secured in the box of the hydraulic press. The bottom plate is loose and slides into a recess in a filling plate, which is free to work up and down in the press box, the bottom plate being provided with a handle for the purpose of sliding it into and out of the recess in the filling plate.—Patent abandoned.

1140 J. LEECHMAN, Hammersmith. *Steam engines.* (A communication.) Dated April 13, 1869.

This invention relates to means of transposing the motion of the piston from the rectilinear to the circular, whereby the ordinary disadvantages, such as the irregularity of motion of the piston in the cylinder or of the revolving main shaft, are obviated. It is, however, impossible to describe the improvements without reference to drawings, and readers are referred to the final specification of this invention filed by the inventor at the Great Seal Patent Office for further information.—Patent completed.

1141 E. DOWLING, St. John's Wood. *Pianoforte action.* Dated April 14, 1869.

This consists in dispensing with the ordinary back in which the adjusting screw is placed, and in applying a screw to the lower extremity of the fly, screwed through such fly in an oblique direction, in order that a button on the end of such screw may rest upon the key, and by being screwed backwards or forwards, thus alter the angle of the fly.—Patent completed.

1142 J. CHANDLER, Mile End-road. *Water waste preventors.* Dated April 14, 1869.

The invention consists of a cistern without division of the capacity of the maximum quantity of water to be contained. The apparatus may be constructed to deliver at one operation or draw. At the lower portion of the cistern is fitted an ordinary valve, communicating with the discharge nozzle or outlet. A second valve is also fitted in the cistern communicating with the source of supply, and by a lever or otherwise it is connected to the valve first mentioned.—Patent abandoned.

1143 P. A. BLAKE, Aberdeen Park, N. *Explosive compounds.* Dated April 14, 1869.

The constituents of this compound are sulphur and chlorate of potash, in the proportion of about one of sulphur to two of chlorate of potash, and the inventor calls his compound, from its properties, the safety explosive.— —Patent abandoned.

1144 A. H. BENTON, Great Queen-street. *Jointing pipes.* Dated April 14, 1869.

This consists in so constructing the ends of the pipes and the packing by which they are made tight that the internal pressure of the liquid or fluid upon the packings shall cause them to be pressed against or into contact with the internal surface of the pipes or the ends thereof, and thereby prevent leakage.—Patent abandoned.

1145 W. H. and T. HACKING and J. CHAMBERS, Bury, Lancashire. *Preparing warps.* (Partly a communication.) Dated April 14, 1869.

This consists, first, of an improved conical self-acting temple, used for the purpose of stretching the cloth to the full width of the reed; second, in the employment of one or more damping rollers, covered with flannel or other porous material for damping the warp as it passes over the back rest of the loom; third, of an improved picking motion; fourth, of an improved loose reed motion; fifth, of an improved one roller positive taking up motion.—Patent completed.

1146 G. KEIGHLEY, Burnley. *Velocipedes.* Dated April 14, 1869.

The cranks are not fixed direct to the driving wheel or its axle, but they act thereon through the intervention of some suitable mechanism (such, for instance, as the well-known "sun and planet" motion), which has the effect of increasing the speed so that the driving wheel revolves at a greater speed than the crank.—Patent abandoned.

1147 J. M'LAUCHLAN, Greenock. *Reburning charcoal.* Dated April 14, 1869.

The ingredients used in carrying out the invention are fireclay, flint, Cornish granite, felspar, Lynn sand, blue Devonshire clay, Cornish china clay, sulphate of baryta, and fired earthenware.—Patent abandoned.

1148 T. AKINSON and R. SMITH, Preston. *Distance indicators for vehicles.* Dated April 14, 1869.

The inventors apply and use a suitable box or casing fastened to the axle at a right or any other convenient angle to the traversing wheel or wheels. This casing contains a suitable train of wheels, which work by friction, each of these or every alternate wheel being covered with india rubber, gutta-percha, leather, paper, or any other suitable material to produce the necessary friction. —Patent abandoned.

1149 J. WHITLEY and S. J. PEET, Leeds. *Moulds and cones for casting metals.* Dated April 14, 1869.

The inventors employ a table in which is an opening of rectangular or other convenient form, and fitted to this opening is a plate which, when in its place, just fills the opening. This plate is arranged to be drawn down out of the opening and replaced by a screw or any convenient mechanical contrivance. The patterns having been prepared, pedestals are made to receive them; each pedestal on its upper surface corresponds in form with the base of its pattern, its sides are parallel or slightly tapered, and its bottom is flat to rest upon the movable plate of the moulding machine, to which it is fixed when in use.— Patent abandoned.

1150 B. W. FAREY, Bermondsey. *Steam engines.* Dated April 14, 1869.

In steam engines in which the steam, after having been worked in one cylinder, is caused to pass into a second cylinder as in what is known as Woolf's engine, the inventor has found that a considerable economy results from heating the steam as it passes from one cylinder to the other. This is done by causing the steam as it is conveyed from one cylinder to the other to be divided into numerous small streams by heated metal surfaces. With this object it is preferred to construct the conductor leading the steam from one cylinder to the other of cast metal plates. The plates are cast with corrugations, except at their edges or margins, where they are thicker than elsewhere, the thickness exceeding the depth of the corrugations. Each plate is planed on both sides, and in this way the edges or margins are trued, whilst on one side of the plate the tops of the corrugations are simultaneously levelled. The plates thus prepared are placed one over the other, so as to form a pile of numerous plates, and they are held together by screw bolts.—Patent completed.

1151 W. WRIGHT, Mostyn. *Treating ores.* Dated April 14, 1869.

The inventor takes any suitable ore, such as the refuse of burnt copper pyrites, and, after reducing it to powder, roasts or calcines it till all the sulphides of the metals are decomposed. He then places it into tanks fitted with suitable false bottoms, and adds weak muriatic acid and water, pumping it through until nearly all the copper is rendered soluble, it is then washed with water till all the soluble copper is washed out. The lead and silver remain behind in the ore in the form of chlorides, which are readily dissolved by brine, and are then washed out and afterwards precipitated with sulphide of sodium.— Patent abandoned.

1152 J. H. JOHNSON, Lincoln's Inn-fields. *Burning liquid hydrocarbons.* (A communication.) Dated April 14, 1869.

The apparatus consists of a gas generator or receiver, the bottom of which is provided with a manhole. A series of upper gas jets or burners is fitted into the top of the generator. Reverberating cups surround the burners, and the lower burners are fitted into the bottom of the gas generator, in order to heat it and so vaporise the oil therein. A chamber for superheating steam is used with the gas, and there is another chamber for heating atmospheric air which may be used either separately or in conjunction with the steam. These steam and air heating chambers are heated by the flame jets from the upper set of burners.—Patent completed.

1153 J. G. JENNINGS, Lambeth. *Building blocks.* Dated April 14, 1869.

The inventor prepares light metal frames, which he places in suitable moulds and charges with slate powder and pitch or other resinous matters; he then applies heat and great pressure, and so forms a solid slab. In carrying into practical effect this part of his invention, he prefers to proceed as follows:—He prepares moulds of the size of the slabs he desires to produce, such moulds consisting of strong rectangular frames jointed together at the corners, and stout top and bottom plates of a size just to enter within the frame. The slabs may conveniently be of a length of 3ft. or 4ft., of a width equal to the thickness of the wall in which they are to be used, and of a thickness of (say) 2in. or 3in.—Patent completed.

1154 T. WHITE, Birmingham. *Nut crackers.* Dated April 14, 1869.

The inventor fixes a rectangular or other shaped frame at the top of a tube. In the tube is a rack, or a screw, or a rod with a series of rings on it, the screw or ringed rod constituting a cylindrical rack. A pinion underneath the frame engages with the rack. To the axis of the pinion a handle is affixed by which the pinion may be turned and the cylindrical rack raised or lowered. The top of the rack carries a plate which, on the rising and falling of the rack, rises and falls in the frame.—Patent abandoned.

1155 W. GRADWELL, Manchester. *Steam boilers.* Dated April 14, 1869.

The inventor places a water chamber or chambers within the flue, consisting of one tube placed within another, and which he calls a case tube. Through the inner and around the outer of these tubes the products of combustion pass, and the water chamber thus formed is connected with the water in the boiler.—Patent abandoned.

1156 C. T. SWANSTON, Twickenham. *Railway trucks.* Dated April 14, 1869.

This consists in interposing ordinary carriage lock gear between the bottom of the railway truck or carriage and the under frame of the railway truck or carriage, each set of lock gear being connected with each axle and pair of wheels, as in common road carriages and waggons.—Patent completed.

1157 A. M. CLARK, Chancery-lane. *India-rubber nipples.* (A communication.) Dated April 14, 1869.

These nipples are usually made of a slightly bulbous form at one end, the other and open end being provided with a rim. These nipples are composed of several thicknesses of india-rubber, which is applied in a liquid state upon a solid mandrel or core.—Patent abandoned.

1158 C. E. BROOMAN, Fleet-street. *Burning liquid hydrocarbons.* (A communication.) Dated April 14, 1869.

This is chiefly applicable to reverberatory furnaces, and consists in causing a current of superheated air or combustible gas, or both combined, to meet the liquid hydrocarbon in a vesicular state above the sole plate of of the furnace. The hydrocarbon is spontaneously inflamed, and a great heat produced. Several applications of this principle are described.—Patent completed.

1159 C. E. BROOMAN, Fleet-street. *Motive power.* (A communication.) Dated April 14, 1869.

This consists in the use of a current of steam and air combined in order to constitute a motive power. To accomplish this a jet of steam is injected into the upright arm of a water or Barber's wheel, and draws with it a certain amount of air. The wheel works in a hermetically closed vessel furnished with valves for regulating the amount of water therein and to allow the escape of the compressed air and steam. The combined current escaping from the arms of the wheel causes its rapid revolution —Patent abandoned.

1160 H. J. WORSSAM, Wenlock-road, City-road. *Sifting machinery.* Dated April 15, 1869.

This consists in lifting casks, boxes or packages from one floor to another by means of a carriage with a tilting platform travelling up and down, being attached to and detached from a continually travelling endless chain.— —Patent completed.

1161 G. BLACK, Spittlegate, Grantham. *Agricultural drills.* Dated April 15, 1869.

This consists in substituting for the revolving barrel and cups as hitherto used rectangular boxes with reciprocating notched slide bars working in them and delivering the said grain or manure at each end of the said boxes into a pipe or tube for conducting the same to the soil or furrow in rear of the coulters. Each box is thus made to supply two drills. The reciprocating notched bars are connected to a cross bar and worked forwards and backwards by a crank, which receives its motion from the travelling wheels.—Patent abandoned.

1162 W. H. BUCK, Stretford. *Velocipedes.* Dated April 15, 1869.

This consists in attaching the ordinary crank pins to connecting rods secured to a block sliding upon a vertical slide bar having a triangular or other suitable shaped section. Upon these connecting rods the plates or rests for the feet of the driver are attached. The slide bar upon which the block slides is situated vertically between the axle of the front guide wheel and the framing supporting the upper end of such slide bar above the framing and in front of the driver, terminating in a handle, by which the vehicle is governed when in motion.—Patent abandoned.

1163 E. COOPER, Laurence Pountney-lane, E.C. *Waterproof coats.* Dated April 15, 1869.

Suppose the coat to be made of double texture, that is, of two thicknesses of material, the inventor inserts or shapes short flexible tubes or passages between them. The openings or mouths of the tubes or passages which come at the inside of the coat are just below that part of the "eye" of the sleeves that come under the arms of the wearer, and the mouths of the tubes or passages situate at the outside of the coat are about one inch more or less below the edge of the "eye" so that in a general way they are concealed from view.—Patent completed.

1164 R. HEYWORTH, Manchester. *Waterclosets.* Dated April 15, 1869.

First, instead of placing the escape-valve of the watercloset at the bottom of the basin and above the stench trays, the inventor places it at the outlet end of the trays and works it by a lever connected to the ordinary handle, the lever releasing the water-valve or tap for allowing a fresh supply of water when the escape valve is opened. Second, for opening by self-acting means the escape valve and water supply valve when the door of the apartment containing the closet is opened from the inside only. The inventor places in the box or frame containing the ordinary latch or fastener a desirable lever connected to a knob inside the door, and places in a guide at the top of the box a rod having its bottom close to the latch and near the end a cross-piece for the double lever to act upon. —Patent abandoned.

1165 A. W. C. WILLIAMS, Bridgeport, U.S.A. *Bottles and jars.* Dated April 15, 1869.

The bottle or jar is constructed with an exterior flange or shoulder surrounding the aperture or mouth, and within this flange is a vertical rim or collar. Around or over this collar the inventor places a flat ring of india-rubber or other elastic material, which lies upon the flange, and immediately under the latter is a groove or channel

The groove is formed to receive a metal ring, which is made in two halves to allow it to be placed in this groove around the neck of the bottle or jar.—Patent completed.

1166 F. J. BRAMWELL, Great George-street, S.W. *Steam engines.* Dated April 15, 1869.

The inventor combines with steam engines condensing apparatus by which the whole or a portion of the steam which has been employed in the engines is turned into water so that the boilers are fed entirely or in part by such condensed steam, thus dispensing with the bringing to the engine of so much water as is equivalent to that arising from the condensed steam, and ensuring the supply of the boiler with pure water to the extent of the water produced from the condensation of the steam.—Patent completed.

1167 J. VIVIAN, Falmouth. *Engines and pumps for mining.* Dated April 15, 1869.

This consists, first, in fitting two pistons in one cylinder; these are driven outwards by the action of steam admitted to the cylinder at or about the middle of its length. The rods of each piston are connected to vertical arms of rocking frames free to oscillate on arms or axles. The inner ends of the rocking frames are jointed to a cross head or coupling plate or plates capable of having an up-and-down movement imparted to it on a guide rod or bar. This crosshead supports the ropes or rods by which the plungers are worked. When the steam has driven the pistons the full length of their stroke the exhaust leading to the condenser is opened, whereby a vacuum is formed. The outer air then acts upon the pistons and drives them inwards to their first positions, to be again acted upon by the steam as before mentioned.—Patent completed.

1168 A. M. CLARK, Chancery-lane. *Compasses and pen cases.* (A communication.) Dated April 15, 1869.

This consists in the adaptation of an ordinary pen nib and holder to one limb of the compass, whereby to facilitate the drawing of circles, the lines of which may be equally as fine as those made by the ordinary compass pen.—Patent abandoned.

1169 J. H. JOHNSON, Lincoln's Inn-fields. *Motive power engines.* (A communication.) Dated April 15, 1869.

This consists of a double action oscillating cylinder worked with a given amount of expansion without the aid of a slide valve. According to one arrangement the full pressure steam (supposing that to be the agent employed) is first admitted on the piston-rod side of the piston, which is of considerably smaller area than the opposite side, and after having produced its effect thereon the steam is cut off and is allowed to operate upon the under side of the piston by expansion only, when it ultimately escapes by the exhaust.—Patent completed.

1170 W. J. COWLMAN and A. DOE, New Windsor. *School desks.* Dated April 15, 1869.

The parts forming the seat and desk are each separately supported on ornamental iron standards. Rising from a common footing on the top of the desk standard is a rule-joint supporting an arm, this arm is divided into two parts working together by a rule joint. The end of the short part of the arm terminates in a plate which is fastened to the desk-board; the action of the joints and arms forms a level table, and by the inserting of a pin in the first-named joint.—Patent completed.

1171 A. K. RIDER, New York, U.S. *Steam valves and gear.* Dated April 15, 1869.

This consists in the construction of the cut-off valve with its ends oblique to the direction of the movement of the main valve, and in so applying the valve to the back of the main valve that it may work transversely thereto without interfering with the longitudinal movement of the latter valve, which has the outer orifices of its steam ports arranged obliquely to correspond with the oblique ends of the cut-off valve. This construction of the valves, seat, and ports permits the point of cutting off to be varied throughout the whole length of the stroke of the piston by the transverse movement of the cut-off valve either by hand or by the governor.—Patent completed.

1172 F. MULLINER, Northampton. *Wheeled carriages.* Dated April 16, 1869.

This consists in fixing two elliptic springs or parts of elliptic springs (commonly called "side springs") to each other and placing them longitudinally on either side of the carriage in connection with the perch.—Patent completed.

1173 The abstract of this specification will appear in a future number.

1174 F. F. WHITEHURST, Putney. *Meshing grain.* Dated April 16, 1869.

This consists, first, in a centrifugal distributor which revolves on a pivot having two branches perforated or slit on the under slide in order to feed the mash tun, or other vessel in a uniform and continuous manner so as to distribute the grain over the whole area of the tun. Second, by means of rousers working in a contrary direction, in causing the greatest amount of agitation in the tun or vessel so as to prevent the conglomeration of the grain when fed in.—Patent abandoned.

1175 R. LEGG, Owen's-row, E.C. *Twisting tobacco.* Dated April 16, 1869.

A table is furnished with a travelling band, on the advancing surface of which the tobacco is fed or laid by the attendant. An upper band or a roller may be made to press upon the tobacco as it passes along the first-mentioned band, and so far the arrangement is only a modification of the construction described in a provisional specification dated 1st October, 1868 (No. 3,013), but instead of the cord of tobacco being passed, as therein described, directly to a common flyer or winding arm, the inventor now compels it to pass between two travelling bands, by which it is consolidated without abrasion of its skin, the said bands being placed at such an angle with the direction of the cord that their surfaces may move in a course corresponding with the twist on the surface of the cord.—Patent abandoned.

1176 W. H. THICK, Kentish Town. *Fret cutting.* Dated April 16, 1869.

This consists in leading a cord from the treadle to a horizontal roller or pulley, round which it is passed several times, and in then leading it to the lower saw jaw or to a part connected therewith. In each movement of the treadle the roller or pulley makes several revolutions alternately in opposite directions, the increased motion thus obtained being imparted by the cord to the lower saw jaw, and consequently to the saw.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated October 26, 1869.

3098 J. Lockwood, Leeds. Improvements in couplings for railway engines, carriages, and waggons.

3099 W. B. Haigh, Oldham. Improvements in circular saw benches.

3100 J. S. Grierson and R. Philips, Broughton Market, Edinburgh. An improved machine or apparatus for bronzing, colouring, and illuminating cards and paper of all descriptions, the same being applicable to bronzing or colouring wall papers.

3101 T. Hoey, Glasgow. Improvements in fireplaces for dwellings, and in arrangements in connection therewith to promote ventilation.

3102 D. Spill, Paradise-terrace, Hackney. Improvements in the preparation and use of solvents of xyloidine, so as to render the same more suitable for industrial applications.

3103 J. P. Rennoldson, South Shields, Durham. Improvements in steam lubricators.

3104 J. Dodge, Manchester. Improvements in machinery or apparatus for forging or shaping metals.

3105 J. H. Nutt, Kingston-upon-Hull. An improved manufacture of wrappers or envelopes used in hydraulic and other presses.

3106 J. Sheldon, Southampton-buildings, Chancery-lane. Improvements in machinery for manufacturing brushes.

Dated October 27, 1869.

3107 T. Briggs, Manchester. Improvements in the manufacture of materials used for packing and other purposes.

3108 T. Dunn, Pendleton, near Manchester. Certain improvements in locomotive steam engines and railway carriages.

3109 C. Simpson, Mount-street, Grosvenor-square, Chase Side, Southgate. Improvements in the manufacture of miniature or toy bricks for the use of children for model or architectural building and for artistic or engineering purposes, together with the apparatus in connection therewith.

3110 W. A. Martin and E. Wylam, Fleet-street, City. Improvements in fuel-feeding and smoke-consuming apparatus for furnaces.

3111 A. Bowater, Sheffield. An improved machine for rolling or shaping metals.

3112 J. Holding and J. Eccles, Manchester. Improvements in looms for weaving.

3113 W. Llewellyn, Park-street, Bristol. Improvements in armour plating ships, applicable also to forts, turrets, shields, and targets.

3114 J. Wakefield, Birmingham. Improvements in the manufacture of carriage and other bolts and pins, and tyre bolts and tyre and other rivets, and in machinery to be employed in the said manufacture.

3115 O. L. Hopson, Birmingham. New or improved machinery or apparatus for reducing the diameter of wire or rods for wire drawing, and for other like purposes.

3116 T. Clark, Cheapside, City. Improved implements adapted for constructing tube wells and driving hollow piles, and in the mode of operating therewith for those purposes.

3117 H. A. Bonneville, Sackville-street, Piccadilly. An improved box for enclosing portraits and photographic cartes.

3118 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the manufacture of sheet iron.

3119 W. A. Ross, Captain in the Royal Regiment of Artillery. Preserving the surface of iron, steel, copper, brass, and other metals or amalgams from being rusted or oxidised by exposure to water or damp air or perspiration.

3120 J. B. Elkington, Newhall-street, Birmingham. Improvements in the manufacture of copper, and in separating other metals therefrom.

Dated October 28, 1869.

3121 H. B. Barlow, Manchester. Certain improvements in knitting machines.

3122 R. Ventress, Stockton-on-Tees, Durham. Improvements in saws, and in apparatus or machinery connected therewith.

3123 J. Watson, Buchanan-street, Glasgow. Improvements in presses for compressing cotton, jute, and other materials.

3124 S. Bennett, Richmond-road, Dalston. Obtaining valuable products from the waste liquors run off from tanneries.

3125 W. Brookes, Chancery-lane. Improvements in the electro-deposition of nickel.

3126 J. W. More, Market-street, Finsbury, and J. Norman, Hoxton-square. Improvements in means or apparatus for clipping horses and other animals.

3127 G. Tubbs, Goodge-street. Improvements in turn buckles for cupboard and other doors, and in the mode of adjusting and fixing knobs or handles thereto, which improvements are also applicable to adjusting and fixing knobs or handles to lock spindles.

3128 L. P. Muirhead, Leadenhall-street, City. Improvements in apparatus for raising sunken ships and other submerged weights.

3129 F. Taylor, Romsey, Southampton. Improvements in apparatus for receiving, drying, and deodorising human excrement.

3130 N. R. Vail, Brixton, Surrey. Improvements in axles for rail and tramway carriages and vehicles.

3131 W. E. Newton, Chancery-lane. Improvements in drawing frames.

3132 S. C. Salisbury, New York, U.S.A. Improvements in steam boilers and generators.

3133 M. Clemens, Boston, Suffolk, Massachusetts, U.S.A. An improved shaft coupling.

Dated October 29, 1869.

3134 J. James, Princes-street, Stamford-street, Surrey. Improvements in apparatus for bending and jointing metallic or other sheets, so as to form boxes, cans, or other vessels.

3135 A. Knowles, Pendlebury, Lancashire. Improvements in machinery and apparatus for cutting and getting coal.

3136 W. W. Girdwood, Lea Cottages, Barking-road, Bromley. An improved gland packing, especially adapted for high temperatures, to be known as Girdwood's self-lubricating metallic elastic packing.

3137 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in coiled or volute springs.

3138 T. Taylor and J. W. Davies, Manchester. Improvements in apparatus for singeing horses.

3139 J. A. Miller, Boston, Massachusetts, U.S.A. Improvements in the construction of steam generators and surface condensers.

3140 C. D. Abel, Southampton-buildings, Chancery-lane. An improved method of, and apparatus for, moulding and casting metal columns.

3141 M., L., and E. Darnbrough, Dewsbury, Yorkshire. Improvements in lubricators for steam engines, cylinders, or other purposes where steam can be applied to melt tallow for lubrication.

3142 A. Nairn, Leith, Mid Lothian. Improvements in steam carriages for common roads.

3143 G. Burge, jun., Rochester, Kent. Improvements in the manufacture of cement.

3144 B. J. B. Mills, Southampton-buildings, Chancery-lane. Improvements in machinery for manufacturing cigars.

3145 J. H. Spencer, Aston, near Birmingham. A new or improved compound for lubricating the journals or necks and bearings of rolls, rotating shafts, and other rotating bodies.

Dated October 30, 1869.

3146 R. J. Everett, West Ham, Essex. An improved process for the manufacture of salts of ammonia from ammoniacal gas liquor.

3147 E. H. C. Monckton, Threadneedle-street, City. Improvements in electricity and means of telegraphing.

3148 J. Elce, Manchester, and W. J. Gradwell, Longsight, near Manchester. Certain improvements in machinery for spinning and doubling.

3149 O. Fahnehjelm, Chiswell-street, Finsbury-square. Improvements in cooking apparatus.

3150 C. Sacre, Manchester, and S. Perkins and W. Smellie, Gorton, Lancashire. Improvements in the manufacture of wrought-iron or malleable metal of steely quality.

3151 J. C. Mewburn, Fleet-street, City. A new or improved photographic process for preparing printing surfaces.

3152 J. C. Mewburn, Fleet-street, City. Improvements in apparatus for feeding boilers, and for raising and forcing fluids generally.

3153 W. E. Gedge, Wellington-street, Strand. A novel method of welding iron or any other metal in the manufacture of every kind of water or gas pipe, boxes for power shafts, axle boxes, tubes, coupling boxes, gun barrels, and generally of all the cylinders and cones entering into the manufacture of firearms, as also in all analogous manufactures.

3154 L. Wray, Ramsgate, Kent. Improvements in motive-power engines.

3155 A. P. Wright, Overton Villas, Brixton, Surrey. Improvements in machinery for breaking, softening, and preparing flax and other fibrous materials.

3156 R. Marsden, Tinsley Park Works, Sheffield. Improvements in pulley blocks or apparatus for raising heavy weights.

3157 T. Moore, South Stockton-on-Tees, Yorkshire, and C. A. Head, Teesdale Ironworks, Stockton-on-Tees. Improvements in apparatus for raising and lowering weights.

3158 W. B. Espeut, Southwick-street, Hyde Park. Improvements in centrifugal drying machines.

3159 A. Minton, Kossuth-terrace, Victoria Park Station. Improvements in electro-coating iron and other metals.

Dated November 1, 1869.

3160 E. de Lagillardaie, Lorient, France. Improvements in the construction of suction syphons for raising liquids and producing condensations and evaporations in vacuum.

3161 W. R. Watson and R. Murray, Glasgow. Improvements in machinery for doubling yarns or threads.

3162 B. Bianchi, Rue de Rennes, Paris. Improvements in the manufacture of cartridges suitable for mining and general purposes, and in the apparatus employed therein.

3163 J. Dewar, Kirkcaldy, Fifeshire. Improvements in the treatment and application of paper waste.

3164 J. Dewar, Kirkcaldy, Fifeshire. Improvements in the manufacture of artificial fuel.

3165 E. Ford, Oakley-street, Chelsea. Improvements in chromatic slides for cornets, trumpets, trombones, and other similar musical instruments, and in devices for operating the same.

3166 R. C. Addy, Lisburn, Antrim, Ireland. Improvements in spindles or flyers used for preparing and spinning flax, cotton, silk, wool, and other fibrous materials.

3167 J. Hargreaves and T. Robinson, Widnes, Lancashire. Improvements in the treatment of pyrites, and in obtaining products therefrom.

3168 A. Thornton, Cleckheaton, Yorkshire, and B. Senior, Heckmondwicke, Yorkshire. Improvements in carding engines or machinery for carding wool or other fibrous substances.

3169 W. Birch, Salford, Lancashire. Certain improvements applicable to sewing machines.

3170 W. and J. Jackson, Halifax, and J. Cowgill, Bradford, Yorkshire. Improved means of preventing the escape of smoke from steam boiler and other furnaces.

3171 P. Jensen, Chiswell-street, Finsbury-square. Improvements in guns for bayonet drill.

3172 B. Tower, Moreton, near Ongar, Essex. Improvements in hot air engines.

PROVISIONAL PROTECTION FOR SIX MONTHS

Has been granted upon Specifications bearing the following numbers:—

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, NOVEMBER 12, 1869.

IRON ARCHES.

THE adoption of cast and wrought iron arches and girders for the purposes of railway traffic was a sad blow to the hopes and expectations of the advocates of the old stone type of construction. Nevertheless, with a laudable desire to make the best of their disappointment, they comforted themselves with the idea that stone bridges would still be employed for ordinary roads, and in other situations where the limitations imposed upon the span, headway, rise, and load were not of the same stringent character. Latterly, however, these pleasing illusions have been dispelled. Bridges have been built over roads, rivers, and in other localities where their duty was not to carry locomotive traffic, and iron, either cast or wrought, has been the material selected. The recent completion of new Blackfriars Bridge affords another instance of the substitution of iron for stone, and in all probability another arch of the latter material will never throw its shadow on the waters of old Father Thames. Omitting other considerations which are foreign to the comparison, what is the chief, the fatal objection, to an arch of stone? In a word, it is the rise. It is absolutely necessary to adhere to a minimum proportion of rise to span, and this adherence becomes impossible under certain conditions of headway and traffic. Engineers are therefore compelled to seek either in another material or another principle of construction for those qualities which they fail to find in that formerly in use. It is true that in arches of iron, either cast or wrought, there is also a limit to the proportion of rise to span, but the ratio is a great deal smaller than in those of stone. Moreover, by special treatment the rise may be confined to points not very remote from the springings, and the crown of the arch be practically perfectly flat. No such a disposition is practicable with stone or brick arches. This adoption of a flat crown was very successfully carried out by Mr. Page in the construction of the present Westminster Bridge. It was effected by introducing a horizontal wrought-iron plate girder for a certain length along the crown of the arch, and bolting it to the haunching or springing segments, which are of cast iron. The span of the largest arch is 120ft., and the length of the wrought-iron girder introduced at the crown 70ft., so that the actual rise of the arch does not increase beyond a distance of 30ft. from each springing.

So far as mere span is concerned, where there is nothing to prevent the proper rise being obtained, a stone arch can bear a very favourable comparison with one of iron. The Grosvenor Bridge over the River Dee, near Chester, has a clear span of 200ft., and is the finest stone arch in existence. On the other hand, the central arch of Southwark Bridge is 240ft. in span, and, in spite of its unscientific design and distribution of material, is yet a fine specimen of cast-iron construction. Its great span and rise give it a bold outline, which unfortunately is very much marred by the bad appearance of the piers, which are little better than those supporting its neighbour of Vauxhall higher up the stream. The expectation that with the substitution of iron for stone in the construction of arches much larger spans would be reached, has not, with one or two exceptions, been fulfilled. With the exception of Southwark Bridge and another to which we shall presently allude, all the arches of the iron bridges over the Thames are inferior in span to that of the stone structure over the Dee. The truth is that the mania, if the term may be used professionally, for large spans has died out. Unless there are no other means available engineers do not advocate the employment of very large spans in ironwork. The reason is that the weight, and consequently the cost, of the superstructure increases in a very disproportionate ratio to the span. There is manifestly, therefore, a certain proportion of span and a certain number of piers—or, what is the same thing, a certain number of spans—which will fulfil the conditions of maximum economy. Colonel Kennedy was the first to reduce this principle to practice, and adopted, with one or two unavoidable exceptions, a uniform span of 60ft. for the spans of the bridges along the whole of the Bombay and Baroda line in India. There is very little doubt but that the span of 60ft. is too small, and greater economy would have resulted from adding ten or even twenty additional feet to it.

In one of the first attempts to substitute cast iron for the older material—stone—in the construction of arches, the transition or the difference was very small, and consisted solely in the adoption of a different material. The same form and the same principle of voussoirs or arch stones were retained in the building of the Sunderland Bridge, with the exception that they were formed of hollow cast iron, and bolted together through flanges cast for the purpose. This was clearly a servile imitation of what had been already accomplished with stone, and iron cannot be correctly said to have been substituted for stone until the "rib" principle came into use. Numerous arches were constructed with cast-iron ribs in which there was not the slightest attempt at accurate designing or scientific and economical distribution of material. So long as they were made strong enough, they answered their purpose thoroughly, and do so still at the present day. The difficulty of obtaining sound and reliable castings of large size induced engineers to construct arched ribs of wrought iron. The two best examples of this nature are the Victoria Bridge, carrying the railway over the Thames at Chelsea, and the magnificent structure recently inaugurated by Her Majesty at Blackfriars. Theoretically, cast iron, from its great resistance to a compressive strain, is the most suitable and economical material to employ for the construction of arches, and it might be used in that situation a great deal oftener than it is. Engineers have conceived a bad opinion of cast iron from the failures with which it has been attended in some isolated instances. At the same time they altogether overlook the important fact that these failures were due not to the unsoundness or weakness of the material itself, but were entirely owing to the circumstance of it being placed in a situation and subjected to strains for the resistance of which it was not adapted. It is very probable that, by a pardonable *esprit de corps*, engineers prefer to lay the blame of these failures upon the material rather than upon the designers. But, as we have now arrived at a more scientific period, and are, from past experience, fully enabled to form a correct estimate of what may be fairly and reasonably expected of cast iron, there is no necessity for refusing to accord to that metal the merit which unquestionably belongs to it.

There are abundance of cast-iron arches carrying the various railways over the suburban roads of our metropolis, which have done duty for twenty or thirty years, and are "as good as new." There can be no question of their strength and stability, and it is difficult to comprehend why some engineers are positively afraid to erect similar structures, but, in their place, substitute others of a more expensive character. Where the span is large and the bridge intended for railway purposes, it is a question for consideration whether wrought iron should not be used instead of cast, especially if the rolling load bears a very large proportion to the fixed weight of the bridge. But, in a bridge intended for ordinary road traffic, where the conditions of the ratio of the fixed to the rolling load are inversed, there is no valid argument against the employment of cast iron within proper limits. The rejection of cast iron in situations where it is peculiarly applicable is a piece of professional pusillanimity which has had its origin in the ignorance and incompetency of some of the members.

THE BOILER EXPLOSION ON BOARD THE "THISTLE."

ON the afternoon of the 3rd inst., a fearful and fatal accident occurred on board H.M. gun-vessel "Thistle," and which was briefly referred to by us last week. This was the bursting of one of her boilers, which resulted in the death of nearly a dozen men, and severe injury to as many more. Such an occurrence, we believe, has never before taken place on board any of her Majesty's ships of war, and it is a matter of the greatest wonder how the present calamity originated. We have heard several surmises upon the point, but pending a thorough examination and the judicial inquiry which is now taking place, we forbear comment, and simply give an outline of the circumstances of this melancholy catastrophe. The "Thistle" is a double screw composite gun-vessel of 465 tons, and 120-horse power, carrying four guns. She was the last vessel constructed at Woolwich Dockyard, and just previous to the closing of that establishment was ordered to Sheerness to fit out and get ready for sea. The "Thistle" was fitted with two pairs of engines which had formerly belonged to gunboats. She had three boilers, two of which were condensers, and the third a high pressure boiler. Steam was got up on the morning of the 3rd inst., and the vessel started on a trip to the Maplin Sands for the purpose of testing her speed over the measured mile. The greatest care appears to have been taken by Mr. W. Williamson, the chief inspector of machinery afloat, and other officers, that everything was in proper order for the trial. Not the slightest defect was perceptible in either engines or boilers, and it was thought the trial would prove more than ordinarily successful. On reaching the Sands the "Thistle" was put on the measured mile, the condensing boilers only being first used. After a series of runs with those boilers, it was determined to try the vessel's speed with the high-pressure boiler. This was accordingly done, and two runs successfully made. On turning for the third run it speedily became evident that some very serious mishap had taken place in the engine-room. Mr. Williamson, in company with Mr. Bannister, chief engineer of the factory, had gone on deck only three or four minutes—leaving Mr. William H. Roberts, the engineer in charge of the vessel, and a number of engineers, fitters, and stokers, in the engine-room—when volumes of steam and smoke rushed up the hatchways and plainly indicated the calamity. On the steam clearing away from the engine-room a descent was made, and the bodies of the dead as well as those of the injured were found just as they fell when overtaken by the destructive blast. The chief endeavour was to get the wounded living men on deck; and very opportunely a private steam tug, named the "Rescue," belonging to Gravesend, the crew of which perceived that something was amiss on board the "Thistle," ranged up alongside, and her master (Forbes) in the most praiseworthy manner conveyed the injured men to Sheerness harbour.

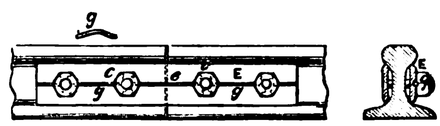
Such is the lamentable history of this catastrophe from an outside view; a record from the engine-room is given by Mr. John

Edgar, an engineering student, in the following words:—He was attending the counters, and was standing in the centre of the engine-room. Mr. Smithers was close to him, and two men, Daer and Mason, were watching the indicators. Suddenly, without any warning, and unaccompanied by noise, he found himself surrounded by what he terms a flash of white light. This was as suddenly succeeded by total darkness. He jumped, or was carried, over the starting levers, and found himself at the bottom of the hatchway ladder. In another instant he was on deck, where he lay in a fainting state. The high-pressure boiler was placed in midships between the two condensers, and an investigation has shown that one of the plates had cracked to an extent sufficient to allow the whole of the steam to escape, as it were, with one rush. The volume, having no other vent from the stokehole than by way of the engine-room and hatchway leading therefrom, instantly enveloped the whole of the unfortunate men in steam, killing or seriously injuring every one in the engine-room. These are the main facts of the case, which we leave without comment at present, except to observe that the explosion appears to be unaccountable. The manner in which it occurred was simple enough, and yet it is equally inexplicable, at least upon present information. We are told that the boiler which exploded had been tested recently under hydraulic pressure in the ordinary way up to 180lb. on the square inch, and during the trial trip it was only being worked at a pressure of 70lb., by no means an excessive pressure for a high-pressure boiler. Suddenly, without any loud report, the plates split asunder, and a volume of intensely heated steam filled the stokehole and rushed on into the engine-room, scattering death around. There remains a mystery which may be cleared up during the investigation, but at present can only be accounted for upon the hypothesis either of a lack of careful supervision or of an overstrained economy which at present obtains in certain Admiralty departments.

METHODS FOR PREVENTING THE LOOSENING OF NUTS.

A NUT that is screwed well home and never subjected to any shocks or vibration would remain in its place until it literally rusted away. The case is very different when it is exposed to incessant shaking and disturbance, and numerous have been the patents and inventions taken out to secure its immoveability under all conditions of local derangement. Obviously, the most practical example presenting itself is that of the bolts and nuts belonging to the permanent way of a railway. It is difficult to imagine an instance where a nut could be exposed to a severer trial than it undergoes in that situation. The commonest method of securing a nut is either to employ a second nut or a pin. A second nut is of no practical use whatever, for the cause that loosens one will infallibly loosen the other. A pin prevents the nut ever unscrewing to such an extent as to separate from the bolt, but has no effect in preventing its loosening. A chronological glance at the more important patents which have been obtained for the purpose under notice shows that within the last few years no less than seventeen have been taken out. This list does not include a large number which never came into practical operation, and, in fact, died as soon as they were born. Among the principles embodied in the former number, the most general are those of keys, grooves, peculiarly shaped washers and discs, and threads of different sizes and directions. The annexed cut represents one of the most recent methods, patented by M. Bouchacourt, and which consists in the employment of a grooved fishplate. There are very few railway companies who adopt any especial means of preventing the loosening of the bolts and nuts in the joints of the rails. When they are loosened they are re-tightened by hand, and the alternate operations are in constant repetition. The ordinary rail fishplate is represented in plan and section in the cut, and the method of making good the joint presents the following points of difference from that in common use. One of the plates E has a longitudinal groove *e* in it, which passes through the centres of the four bolt holes. The bolts are of the usual description, but the under or bearing surface of the nuts is provided with small radiating grooves, and the washer is dispensed with, but a pin *g* is employed, which is the special characteristic of this plan.

FIG. 1. FIG. 2.



In putting the joint together the only point to be attended to is that two of the grooves in each contiguous bolt should coincide with the groove in the fishplates, a condition readily ensured. Each pair of nuts is then ready for the introduction of the small pin *g*, which has been slightly bent to allow of its two ends being inserted at the same time in the cylindrical holes formed by the superposition of the grooves in the nuts and that in the fishplate. A blow or two of a hammer suffices to straighten the pin, and the keying of the nut is complete. The most economical manner of applying this principle is to have the groove made in the fishplate when it is manufactured, but ordinary fishplates can have it cut in them if required, although at a rather larger cost. It is also quite possible to employ this method when the fishplates have no groove, but it is evident that the keying is not so well performed or so efficient as when the key actually fits into the plate as well as the nut. When an ungrooved fishplate is used, the section of the key is rather different from that already described. It is thicker in that part which lies between the two adjoining nuts, and is fined down only at the ends. In making the nuts and fishplates the grooves could be introduced without any extra cost, so that the only increase beyond the outlay for ordinary joints would be the price of the keys and the royalty. Taking the rails at an average length of 20ft., this would amount to about £1 10s. per mile, a very trifling sum for effecting the purpose. This system of M. Bouchacourt has been tried for the last couple of years and found to answer very well. It has been very successfully applied to the railway from Paris to Lyons, as well as to other lines in various parts of the continent. Besides fixing the key in its place, it is necessary to be able to take it out. This is easily done by introducing a strong chisel or other suitable instrument between the key and the fishplate, and "prizing" it up until it assumes the bent form it had before it was inserted in its place. A fresh turn can then be given to the nuts, and the key replaced as before. Sometimes it might be requisite to use other means for undoing the joint, when that just described might not be efficacious. In that case, the nuts are turned by a spanner until they cut off the ends of the key, which then drops out. By this operation the key of course is destroyed, but the cost of replacing it is too trifling to deserve consideration.

DR. LIVINGSTONE.

THE friends of Dr. Livingstone were much gratified on Monday evening last by hearing read a long letter from our veteran explorer to the Earl of Clarendon, dated July, 1868. The letter was a long one and gave many interesting details of the great traveller's proceedings and researches. Dr. Livingstone has also written to Sir Roderick Murchison, and from these combined communications we learn that Dr. Livingstone has traced a chain of lakes, connected by rivers, from the tracts south of the Lake Tanganyika to south lat. 10deg. to 12deg., and he conjectures that these numerous connected lakes and rivers are the ultimate southern sources of the Nile. When he wrote he was about to travel northwards to Ujiji, on the eastern shore of Lake Tanganyika, where he expected to find some information from home, of which he had been entirely deprived for two years, as well as to receive provisions and assistance. As Dr. Kirk adds, in a letter to Sir Roderick, "You knew long ago of his safe arrival at Ujiji," we may infer that before this time he will have satisfied himself whether any of the South African waters flow into the Equatorial Albert Nyanza of Baker, of the existence of which great lake we now learn that Livingstone was cognisant. If this determination has been arrived at, Livingstone will have gloriously solved the great problem of African geography, and will have proved by actual observation that Ptolemy, seventeen centuries ago, really placed the sources of the Nile in about their true latitude, a view which has of late years been sustained by Beke, Arrowsmith, and Findlay. It is gratifying to learn that in consequence of the goodwill and letters of the Sultan of Zanzibar, Dr. Livingstone has been most hospitably treated by the Arab traders in the interior, of whom he writes in the most grateful terms. He says, writing to Dr. Kirk, "I am greatly obliged by the Prince's letter, and beg you to say so to his Highness. I don't know which of his subjects have served me most where all have shown kindness and goodwill."

BLACKFRIARS BRIDGE AND HOLBORN VIADUCT.

THESE two important City improvement works were opened by Her Majesty on Saturday last, the circumstance being everywhere marked by loyal demonstrations and rejoicings. The full descriptions, with illustrations, which we gave of both these works last week renders it unnecessary for us further to allude to them here. After the ceremony of opening, a great deal of work had to be performed in clearing away the temporary pavilions and stands which had been erected both on the Bridge and the Viaduct. This done, they were thrown open to the public—the Viaduct on Monday, and the Bridge on Tuesday morning. There still remain various minor details to be completed upon the Bridge, and some of importance upon the Viaduct. We regret to find that the traffic over the Farringdon-street Bridge of the Holborn Viaduct has had an injurious effect upon the granite columns of that structure. An examination shows that several of the blocks of which the columns are composed have settled irregularly. The edges are brought close together in some cases, resulting in cracks and chips, the opposite sides of the columns showing a wide space between the stones. The lower block in the second, third, and fourth columns from Farringdon-street on the east side appear to be cracked through, which indicates that these blocks are not nearly deep enough to resist the pressure brought upon them. The lower block of the third shaft on the west side is badly cracked, whilst the block immediately over it has a serious crack extending upwards some 3ft. of its length. There are many other flaws and defects of the same character, which we much regret to see in this portion of the structure. We can only attribute it at present to a want of proper care in setting the masonry, as well as in having the lower blocks of the granite shafts too shallow, and thus easily crushed. The

lower stones do not appear to have been truly set, and the weight and vibration of the traffic have discovered the inequalities of the bedding, and have caused shifting and cracking. We intend to give this subject further consideration next week; in the meantime we would suggest that this failure teaches a practical lesson of the wide difference between haste and promptitude.

NOTICES OF BOOKS.

THE great changes which a few years bring about in the practice of our machine shops renders it necessary that those works which are written for the instruction and direction of young engineers and students should be from time to time modified or even re-written. It is well, too, when a new mind is brought to bear upon the subject, provided that mind be of a practical turn and capable of imparting sound and useful knowledge. We are therefore glad to see a work of a specially practical character on the modern practice of our workshops,* from the pen of Mr. John G. Winton, whose name has often appeared in our pages in connection with various useful suggestions. The present treatise is classed as one of Weale's rudimentary series, No. 164, and most ably it fulfils its appointed position. It is the result of the author's experience in a wide field of practical engineering, and contains a fund of useful information upon the varied subjects of marine, land, and locomotive engines, floating docks, dredging machines, bridges, shipbuilding, cranes, and agricultural engines, besides a variety of miscellaneous information. We have here not merely a code of well-known and oft-repeated rules and formulæ for the various requirements of this class of work, but we have the results of the author's long experience, which makes itself known in a variety of useful ways. And the reader has not merely described to him the various parts of machines or the perfect engine, but he is frequently taken through the workshop with the parts themselves, so that he really attains a knowledge—so far as a book can impart it—of their actual production. Then, again, there are specifications and estimates of existing work which enter into all the details of weights, dimensions, materials, and cost. Where all is useful and to the point and purpose it is difficult to select one subject more than another for special notice. We may, however, refer to the chapters on land and marine engines and shipbuilding as embodying much that will be found useful in practice. The treatise is well illustrated with intelligible woodcuts, which complete it as a sound guide to the present practice of our workshops.

The twenty-eighth volume of the Transactions of the Institution of Civil Engineers for the session 1868-9† has been lately published. It contains fifteen papers on various subjects, all of which will be found of great value to the profession. As abstracts of these papers have for the most part appeared in our columns, it will only be necessary here to refer to them categorically. They are as follow:—"On Lighthouse Apparatus and Lanterns," by David Marr Henderson, Assoc. Inst. C.E.; "On the Roman Rock Lighthouse, Simon's Bay, Cape of Good Hope," by John Frederick Bourne, M. Inst. C.E.; "Description of the River Witham and its Estuary, and of the various works carried out in connection therewith, for the Drainage of the Fens and the improvement of the Navigation," by William Henry Wheeler, M. Inst. C.E.; "On Machines Employed in Working and Breaking Down Coal, so as to Avoid the Use of Gunpowder," by Samuel Parker Bidder jun., Assoc. Inst. C.E.; "On Coal-Getting Machinery, as a Substitute for the Use of Gunpowder," by Charles John Chubb; "Description of the New Ferry and the New Brighton Piers and Landing Stages on the River Mersey, near Liverpool," by Henry Hooper, Assoc. Inst. C.E.; "On the Mauritius Railways—Midland line," by James Robert Mosse, M. Inst. C.E.; "On the Lagoons and Marshes of Certain Parts of the Shores of the Mediterranean," by D. T. Ansted, M.A. F.R.S., For. Sec. G. S., F.R.G.S., &c.; "On Sinking Wells for the Foundations of the Piers of the Bridge over the River Jumna, Delhi Railway," by Imrie Bell, M. Inst. C.E.; "Description of Apparatus for Excavating Under Water, and for Sinking Cylinders," by John Milroy, Assoc. Inst. C.E.; "On American Locomotives and Rolling Stock," by Zerah Colburn, M. Inst. C.E.; "Experiments on the Standards of Comparison Employed for Testing the Illuminating Power of Coal Gas," by Thomas Mesham Kirkham, M. Inst. C.E.; "On the Outfall of the River Humber," by William Shelford, M. Inst. C.E.; "Description of the Low Water Basin at Birkenhead," by John Ellacott, M. Inst. C.E.; and, "On the Present State of Knowledge as to the Strength and Resistance of Materials," by Jules Gaudard, C.E., Lausanne (Translated from the French by William Pole, F.R.S., M. Inst. C.E.). Abstracts of the discussions are annexed to the papers upon which they have taken place, and the papers are copiously illustrated by folding plates. The volume has been ably edited by Mr. Forrest, who deserves credit for the satisfactory appearance of the proceedings.

† "Modern Workshop Practice." By JOHN G. WINTON, Engineer. STRAHAN and Co., 56, Ludgate-hill, London. 869.

* "Minutes of Proceedings of the Institution of Civil Engineers." Edited by JAMES FORREST, Assoc. Inst. C.E., Secretary. London: Published by the Institution, 25, Great George-street, Westminster. 1869.

The Transactions of the Institution of Naval Architects for 1869 have just reached us. The present forms the tenth volume of valuable papers upon naval matters, which commend themselves to all engaged either in the construction or the navigation of ships. These Transactions—which are published at the office of the Institute, 9, Adelphi-terrace, London, W.C.—are well edited and well got up, forming a handsome and at the same time a handy volume, and being illustrated with some excellent lithographs. The work contains the series of papers read at the annual meeting of the Institute, held in March last, together with the discussions which took place thereon. Of these papers—eighteen in number—we have but little to say, inasmuch as a full report of them, with our comments upon them, appeared in our pages at the time they were read and discussed. They refer to all the varied subjects connected with the construction and navigation of both sailing and steam ships, including armour plate resistance, liquid fuel progress, the qualities of boiler plates, strains in propeller shafts, copper and zinc sheathing, &c., &c. One thing, however, before closing, we feel bound to notice. We protest against the conversion of the Transactions of a scientific body into a medium for advertising a comic periodical, and that, not one of the highest order of merit. Inside the volume of Transactions under notice, we received two copies of a circular sounding the praises of a comic journal which we shall not advertise by naming, but shall simply refer to as one of the most recent of the mushroom tribe which have of late made their appearance, and the circular of which is written in the most painfully alliterative style. We know not with whom the fault lies in thus allowing the Transactions of a respectable body to be made the means of distributing trashy puffs, but we trust that means will be taken to prevent the repetition of such an undignified proceeding.

We continue to receive with regularity the monthly parts of Mr. Bourne's valuable work on the steam engine,* those for June and the intervening months to November inclusive being now before us. Part XIII.—that for June—contains the conclusion of a long list of improvements in the steam engine, and the commencement of a chapter on air and gas engines. The first idea in this direction appears to have been recorded in the patent office in 1794, when Mr. Robert Street obtained a patent for producing an inflammable vapour force by exploding the vapour of the spirits of tar or of turpentine in a cylinder mixed with air, the bottom of the cylinder being kept hot to vaporise the liquid, and the vapour being inflamed by a touch-hole, as in a gun. The piston, which was a solid block suspended on a rod at the end of a beam, was shot up by the explosion, and gave motion to a pump by which the power was communicated to any mechanism requiring to be driven. It is a long stride from this primitive device to the present perfected form of our gas engine, but its principle is there clearly indicated. This division is continued into Part XIV., where it is concluded. The next chapter commences with particulars of various projects for the production of motive power, selected from amongst the rest for their superior practical character. This subject embraces the many improvements which have been made from time to time in boilers and furnaces, some of which are due to Mr. Bourne himself. One of these improvements is that made in furnaces with a view of fitting them to burn coal dust, which will probably yet become an important article of fuel. This branch of the subject is still under consideration in Part XVIII., for November, the whole being profusely illustrated with wood engravings, and including the well-known systems of Ericsson, Lenoir, and others. Besides the woodcuts, each part is accompanied by large folding plates, which give examples of engines of the most modern and improved construction.

* "Examples of Modern Steam, Air, and Gas Engines, of the most recent approved types." By JOHN BOURNE, C.E., London LONGMANS and Co., Paternoster Row. 1869.

We have from the Commissioners of Patents, Southampton-buildings, Chancery-lane, a copy of the abridgements of specifications relating to acids, alkalies, oxides, and salts, from the year 1622 down to 1866. This series, besides embracing all inventions relating to the making or obtaining by any direct or indirect methods of acids, alkalies, oxides, or salts, includes inventions relating to the making or obtaining of several elementary bodies. Amongst these are bromine, carbon, chlorine, fluorine, iodine, hydrogen, nitrogen, oxygen, and sulphur, and some compound substances or bodies, such as cyanogen, none of which of themselves possess either the property of an acid, an alkali, an oxide, or a salt, but which in the process of their production are accompanied very frequently by the formation of one, two, three, and even in many instances of all of these substances in one and the same invention. The value of these abstracts are now so well known and so thoroughly appreciated that it is superfluous to say anything in their favour. Inventors and the public are under a special obligation to Mr. Benet Woodcroft and his able staff for the abstracts which so greatly facilitate inquiry and research into the numerous subjects covered by the specifications.

"Half Hours with the Stars" is the title of a very useful work by Mr. R. A. Proctor, F.R.A.S., which has been recently published by Mr. Hardwicke, 192, Piccadilly. It is a plain and easy guide to the knowledge of the constellations. It consists of twelve well executed maps, which show the position of the principal star groups, night after night, throughout the year. There is an interesting introduction, and each map is accompanied by a separate explanatory statement. The work is plain and simple, and "teaches the stars" in a way which cannot be misunderstood.

The "Popular Science Review" (Hardwicke) for the present month has for its opening article Dr. Miller's lecture on the method of determining the compo-

sition of the sun and other heavenly bodies by the spectrum, which was delivered to the working men of Exeter in August last. An abstract of this paper has appeared in our pages, but we would refer our readers to the whole subject, which is beautifully illustrated in the "Science Review," and is well worthy of careful perusal. Following shortly after this paper is one in which Mr. R. A. Proctor ably discusses the question "Are there any fixed stars?" He refers to Mr. Huggin's method of mapping stellar motions, and observes that it will be a matter of extreme interest to determine by this method whether the stars which seem to form drifting systems have a community of motion of recess or of approach. Should this be the case no doubt could possibly remain that the stars form sets or groups, and that there is no approach to that generally equable distribution described in our popular treatises of astronomy.

The "Journal of the Royal Agricultural Society of England," published by John Murray, Albemarle-street, contains its usual complement of valuable articles upon agricultural subjects. There is a very useful series of farm reports, seven in number, which describe the methods of farming adopted in various districts. The point of main interest to most of our readers will of course be the report on the exhibition and trial of implements at the Manchester Great Show in July last. As we reported fully upon the subject at the time, we need not here further refer to the matter, except to observe that the report now before us is an elaborate and well-digested production, and of course embodies detail information which our limited time and space naturally prevented us giving. The reports of the judges of the various classes are here given, and some conception of their work may be formed when it is stated that they had to wander through upwards of seven thousand articles to select seven for medals!

Mr. Henry Dircks, one of the inventors' ablest champions, read a paper upon the statistics of invention before the British Association at Exeter. This paper, which is published in pamphlet form by Messrs. Spon, 48, Charing Cross, illustrates the policy of a patent law, and forms the second part of a letter addressed to Lord Stanley, now Earl Derby, upon this important subject. It is of course a further answer to Mr. Macfie's ill-advised motion, and still more ill-written book of odds and ends, in favour of the abolition of patent law. Appended to the paper is a report of the discussion which took place after its reading, and in which the benefits of the patent laws are strikingly illustrated.

Mr. E. B. Marten, the chief engineer to the Midland Steam Boiler Inspection and Assurance Company, has compiled some useful information upon the subject of steam boiler explosions. We first have a paper upon the subject, which was read by Mr. Marten before the Institution of Mechanical Engineers in August, 1866, and which points out the great importance of inspection as a means of prevention. This paper is followed by consecutive statements of the boiler explosions for the years 1866-7-8. The whole of the matter is fully illustrated, and affords accurate and useful information, which will prove useful to all interested in the safe working of boilers. The volume is published by Messrs. Spon, of Charing Cross.

Mr. G. W. Jones, in a pamphlet published by Davies and Co., Finch Lane, Cornhill, and in which bombast and big type are alike conspicuous, addresses himself to the "people of England," and propounds a scheme for universal penny railways. He is careful to explain that he has no personal object to serve, and it is well that he has not, or he would not attain it by the present means. The pamphlet is too much in the *ad captandem* and stump-orator style to fix our attention at present, but if Mr. Jones will obtain the sanction of one or two of our leading railway managers to his scheme, we promise to give it our careful and dispassionate consideration.

PHOTOGRAPHY.

The Photographic Exhibition.—The American Solar Eclipse Photographs.

THE annual exhibition of pictures by the Photographic Society of London is now open to the public free, at the rooms of the Architectural Association, Conduit-street, Regent-street. The collection includes very many fine photographs, and it is perhaps the best exhibition ever brought under public notice by the society. Among the photographs are some of great interest taken by Captain Lyon, in India, showing the rich and elaborate nature of the architectural monuments of that remarkable country. There are also specimens of pictures by the various permanent carbon photographic processes, as well as some of the old Daguerreotypes. Breese's stereoscopic views are a great source of attraction, being very fine specimens of instantaneous photographs printed as transparencies; one of them, of a wave breaking on the seashore, is specially good, as even the drops of spray in the air have been taken, so rapid was the exposure. Some combination pictures, by Robinson and Cherrill, are beautiful specimens of photography, so also are some of their portraits, especially that of Mr. S. C. Hall. Colonel Stuart Wortley exhibits some very fine sea and cloud effects, labelled as moonlight scenes, though they are not so in reality. Perhaps the most remarkable pictures on view are some cabinet portraits by Reutlinger, which are marvels of beauty; the negatives from which they were taken having evidently been laboriously "touched up" by a master hand, so that the pictures cannot be considered to be samples of pure photography. The pictures of M. Adam Salomon, which attracted so much attention last year, have found many imitators in England, as proved by the pictures at the exhibition. Some photographic enamels, by Mr. Henderson, show progress in one very beautiful phase of photography, and a very valuable phase too, because of the permanence of the pictures. They require improving a little in richness of tone and colour. Some large pictures of the scenery of the Vale of Neath, by Mr. F. C. Earl, are also leading features in the exhibition. Visitors ought to know that there are no moonlight views in the exhibition, and that the pictures so labelled are really under-exposed views of sunlit scenes, the inscriptions upon these pictures not being exactly truthful. One fault in the exhibition is, that the pictures have not inscribed upon them the names of the processes by which they were taken.

A very valuable weekly periodical called "Nature" was issued for the first time on November 4 by Macmillan and Co. Thirty or forty of the leading philosophers of the day, including Darwin, Tyndall, Huxley, Lockyer, Stewart, and Thompson, are among those who intend contributing to its pages. The first number contains, among others, an interesting article by Mr. J. Norman Lockyer, F.R.S., on the photographing of the solar eclipse in the United States, and a woodcut copied from one of the photographs proves that the Americans have as yet succeeded better than anybody else in getting good pictures of a total eclipse of the sun.

TELEGRAPHIC NOTES.

LAST Saturday morning the "Great Eastern" left Portland, on her way to Bombay, carrying the British-Indian deep sea cable, and fitted with all appliances for submerging it. Her tanks contain 2,735 nautical miles, and her companion ships, the "Hibernia," "Chiltern," and "Hawk," carry among them 1,225 miles more, making a total of 3,600 nautical, or about 4,050 statute miles. This length will suffice for the communication between Bombay and Suez by way of Aden, and will join the present Malta and Alexandria line. As stated on a previous occasion, another cable is projected, to be laid from Falmouth to Gibraltar and Malta, and its completion will unite Bombay and the British fortresses in the Mediterranean along one line of submarine telegraphy which will be unbroken except at Suez.

A fortnight since we printed a letter showing the careless manner in which the telegraph system between this country and Portugal is conducted. As an appropriate sequitur we append the following from the "Bombay Gazette." That journal says of the new line of telegraphic communication with Europe, *via* Russia, which was opened a few weeks since:—"It is but due to it that we should acknowledge in our overland summary the remarkable service it has rendered to India as a means of transmitting public news and private advices. The following telegrams, printed as received, speak for themselves; they are Reuter's:— London, 17th.—Alderman salomon titus salt baromds crawfords refused corranclay another agriablan assination ireland carecton butury catholic archbishop Armach. 21st.—Days insurrection volontry Barcelona refused disarm erektea bariechres tatetupi send amaise of severe fighting orders restored Jestic feary pattot cornuned sonied. 22nd.—letter popp Rumming Kumming contat allap non—Catholics auter encommedial Concil for discussion from already contend abitury generally chained hoals ford times braves suppes deserved with drawtoc to presented spot his government saying excepted instructions and Washington government disavowes, proedirm a amors King Portugal accepting throne shrit abdicating favour Creditary prince secretary governor tarasend—assassinted republican mob for attempting put down revolutionary flows bank hole Canbreisen discute runoured large withdrawal to-morrow sneely telegraphed Washington Spain resolved not negociate for sale Empereur Napoleon have given audience to Lord Clarendon prince prussian Coning Constantinople afterchetir suez brashop excited. 27th.—Having change prefory by shareholders against manger directors Albert Assurance for consgnai conweed Saturday Ignidotlors examined no cancil fremd on part directors cose adanaten. 29th.—Spisow clarundas al ounheral association lord been an continent head opportunity collectired opinions seen persons who exercise influence on bestiwos Europe and believe at no time since prussians austrian paer oxisted faviar paus pant monte montement blessing peace."

The British Indian Extension Telegraph Company have given the order for the manufacture of their cable (to be laid between Ceylon and Singapore), accompanied by the necessary payment to the Telegraph Construction and Maintenance Company.

It is stated that the telegraph office in the Lombard Exchange and News-room will be connected with the central Government office by a pneumatic tube, and that it is the intention of the Postmaster-General to use this station for postal as well as telegraphic business.

The number of messages through the French Atlantic Telegraph during the week ending the 6th of November was 855, the cable charge thereon being £1,928, showing a reduction of £667 from those of the preceding week.

The following telegram relating to the Government Indu-European Telegraph, was received last Saturday:—

Cable ship "Calcutta," Nov. 1, 6·30 p.m.

"First November, noon. Three hundred and twenty miles cable submerged. Tests excellent All going well."

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

Preparation of Caustic Baryta—New Dressing for Black Stuffs—Effect of Heat and Cold on the Illuminating Power of Gas.

WE have on more than one occasion referred to processes for the manufacture of caustic baryta, the production of which at a cheap rate, it has been truly said, would revolutionise our alkali manufacture. The matter commands a good deal of attention among French industrial chemists, and a process has been brought before the Mulhouse Société d'Encouragement which up to a certain point is quite satisfactory. Necessarily, the first step is the reduction of the insoluble sulphate of baryta to sulphide. There is but one way of effecting this, and that is by roasting it

with small coal or other carbonaceous matter, but the management of this part of the process demands care. Some air must be admitted to the furnace, but if too much is allowed to enter, the sulphide produced is again oxidised to sulphate. By taking care, however, it seems that a large proportion of the sulphate employed can be reduced in one operation. The next step is to dissolve the sulphide of barium out of the roasted mass, which is done in ordinary lixiviating vats. We have now to remove the sulphur from the sulphide, and supply its place with oxygen. The inventor of the process we mention does this by digesting the solution with hydrated oxide of zinc, which exchanges its oxygen and water for the sulphur, and the zinc is precipitated as sulphide. This process it is admitted is quite practicable, and even economical, but not sufficiently so to allow of its use in the preparation of caustic soda from sulphate of soda. If the sulphur could be extracted from the sulphide of zinc and utilised, the cost of the process would be so much reduced as to make it a commercial success, but there are difficulties in the way of this which have not yet been surmounted. Two modes of treating the sulphide of zinc have been tried. One of these is roasting it and collecting the sulphurous acid. The other is allowing the sulphide to oxidise to sulphate of zinc. We give this process for what it is worth. It appears to be a great improvement on the methods previously tried, and gives us hope that we shall soon see caustic baryta a common and profitable manufacture.

A new kind of dressing for black woollen stuffs is used in Germany. The dressings generally in use are colourless, but the new invention is really a black dye, to which albumen is added. A practical dyer will see at once how a bath of this kind can be prepared. We can say from experience that a dressing of this kind gives a brilliant face to goods while adding somewhat to weight.

It is well known that variations of temperature considerably affect the illuminating power of gas. In winter less light is obtained, and more light may be got from gas by heating it. The exact extent, however, to which the illuminating power is affected has only recently been ascertained by Vogel. He passed gas through a U-shaped tube, which he immersed, in the one series of experiments, in ice and certain freezing mixtures, and in the other set, in boiling water and in a bath of heated paraffin. The gas was burned directly from the tube before any elevation or reduction of temperature could take place, and the light was compared with a normal flame, the light-giving power of which at 65deg. Fah., was taken as 100. Then, for reduced temperatures, we have the following results:—At the freezing point (32deg. Fah.), the illuminating power was only 76, and at 4deg. Fah., only 33. These figures show that the influence of cold is very considerable, much more considerable indeed than that of heat, for gas passed through boiling water, and compared as before with the standard flame, showed an increase of only 4 per cent., and heated in a paraffin bath to 320deg. Fah., an increase of only 18 per cent. in illuminating power was observed. The loss of power from the application of cold is the result of the condensation of hydrocarbon vapours. The gas reduced to 4deg. by the immersion of the tube in a freezing mixture left a congealed mass on the sides of the tube, which Vogel examined and found to contain benzol, ammonia, and nitric acid. The presence of this last no one could have expected, and it is very remarkable that it should be produced in the manufacture of gas.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the first ordinary general meeting of the session, held on Tuesday, the 9th inst., Mr. Charles Hutton Gregory, the President, made the following observations on taking the chair:—

Although every member of the Institution in this country has already received copies of the recent communications addressed to the Government of India, it is felt that the Institution ought not to meet for the first time after the vacation without some reference to an attack on the honour of the profession, which has justly aroused, in India and in England, a deep feeling of indignation. On the 18th of October, copies were received here of a notification gazetted by the Public Works Department of the government of India, in which it was alleged that the Governor-General in Council was given to understand that in the civil engineering profession in England it was a recognised practice for civil engineers employed by public companies and otherwise to receive, in addition to the salaries paid them by their employers, commission on contracts given out, or stores and materials ordered or inspected by them, and other like pecuniary considerations for services done, or intended to be done, which were considered legitimate sources of emolument.

The council immediately met, and unanimously passed a series of resolutions emphatically denying that such practices were recognised in the profession, and asserting that any engineer detected in such practices would be held to be guilty of disgraceful conduct, which would disqualify him from being a member of this Institution. Regret was expressed that so grave a charge should have been received and published by the government of India without proper inquiry, as such inquiry would have shown that the charge was absolutely untrue; and, having reference to the grievous wrong which such an imputation, stamped with such authority, was calculated to do to an honourable profession, an appeal was made to the government of India to cause the scandalous statement to be withdrawn. This protest was transmitted to the Secretary of State for India, who only reached London on the 25th of October, but who, on the 27th, amidst the pressure of other public business, received a deputation from this Institution, comprising the President and every member of the Council then in London. The deputation pointed out to his Grace not only the injustice which the notification had done to the whole profession, but also the serious effect which it would produce on the public service in India, as such a disgraceful stigma, cast upon civil engineers as a body, would bring to a crisis the widespread discontent already existing among the civil officers of the Public Works Department; and they submitted that unless the notification were withdrawn, it might be expected that the government of India, at the very moment of taking upon itself the construction of all the public works of that empire, would lose the services of the best of those whose experience would, at such a time, be essential.

The Duke of Argyll promised to investigate the case, and, with the natural instinct of a just and high-minded statesman, has put on record that "he regards with implicit confidence the indignant repudiation by the Institution of any recognition of the practice referred to in the notification." By the mail of October the 29th, the Council forwarded their protest to the Governor-General of India, and sent copies of the correspondence to the many engineers who had addressed them and claimed their intervention. Time will probably throw more light upon the causes and motives of this most ill-advised notification.

If in the engineering profession, as in others, there may be instances of secret dishonesty, such acts are not recognised as legitimate. The profession has not sought to parade its purity before the world, but the members of this Institution know how carefully anyone believed to be unworthy of it has been excluded from this the representative body of the profession; and, although happily such instances have been very rare, and such practices are from their nature most difficult of detection, yet steps have before now been taken, which have issued in some persons charged with misconduct ceasing to belong to the Institution. At the approaching annual general meeting the Council will ask that ratification of their action which they are confident that the members will unanimously and cordially give; and if among the public there be some cynical minds which, while very sensitive for their own repute, can take pleasure in a libel directed against others, the members of this Institution may feel sure that, in vindicating the honour of the profession, they will have the sympathy of all honourable men.

MR. CARLYLE has written to Dr. Longmuir, of Aberdeen, with reference to the inscription on the Keith statue at Peterhead, as follows:—"If you know any likely man in Peterhead, I wish you would tell him that the word '*Hochkirchen*' they have put on the inscription under Keith's statue is an *ugly blotch of error*, much requiring erasure for their sake and his! '*Hochkirch*' was the village where Keith perished; there is no such place as '*Hochkirchen*' in the whole world, nor ever will be. '*Hochkirchen*' is worse than '*Peterheadikin*;' an *incurable* solecism —exactly equal to *Alta-Ecclesiæ*,' of which you can judge! No remedy but cutting out that EN (at whatever cost) and substituting silent granite.

LAUNCH OF THE "BRITON" AND TH "VULTURE."

ON Saturday last the "Briton," unarmoured screw sloop, carrying ten guns, and of 350-horse power, was launched from Sheerness Dockyard. The "Briton" is from the designs of Mr. Reed, chief constructor, and is sister ship to the "Druid," which was launched at Deptford just previous to that yard being closed. She is in form and build nearly the same as the "Eclipse," which was launched from the dockyard in November, 1867, but is 8ft. longer. The following are the dimensions of the "Briton":—Length between perpendiculars, 202ft.; length of keel for tonnage, 193ft 11$\frac{1}{2}$in.; breadth extreme, 36ft. 1in.; breadth for tonnage, 35ft. 11in.; breadth moulded, 35ft. 3in.; depth in hold, 19ft. 7$\frac{1}{4}$in.; burden in tons, 1330 59-94. On the same day the "Vulture," wooden twin screw gun vessel, three guns, 160-horse power, which has been built in No. 2 dock, was floated into the basin. This vessel is sister ship to the "Bullfinch," which was floated from the same dock eighteen months ago. The following are the dimensions of this ship:—Length between perpendiculars, 170ft.; length of keel for tonnage, 151ft. 7$\frac{3}{8}$in; breadth, extreme, 29ft.; breadth for tonnage, 28ft. 8in.; breadth, moulded, 28ft. 2in.; depth in hold, 12ft. 5in.; burden in tons, 662 65-94. The engines of this vessel are being manufactured by Messrs. Rennie and Co.

THE PHOTOGRAPHIC SOCIETY.

THE opening of the session of the Photographic Society took place on Tuesday evening, with a fine display of photographs, at 9, Conduit-street. The increase of artistic qualities was the most marked feature of this exhibition over its predecessors. Mr. Wardley, of Manchester, had some remarkably fine pictures, large in size and treatment; and Mr. R. M. Gordon some of those little gems which are quite *sui generis*. Captain Lyon exhibited some photographs of Indian temples of rare excellence and of great architectural interest; and Mr. Stephen Thompson some fine specimens of Italian buildings. But his *chef d'œuvres* were two pictures of an "Old Kentish Homestead" of the sixteenth century, rich in quaint gables. Messrs. Vernon Heath, Mayall, W. England, Russell Sedgfield, and Beadell and Wilson, and other familiar and excellent artists, were also well represented.

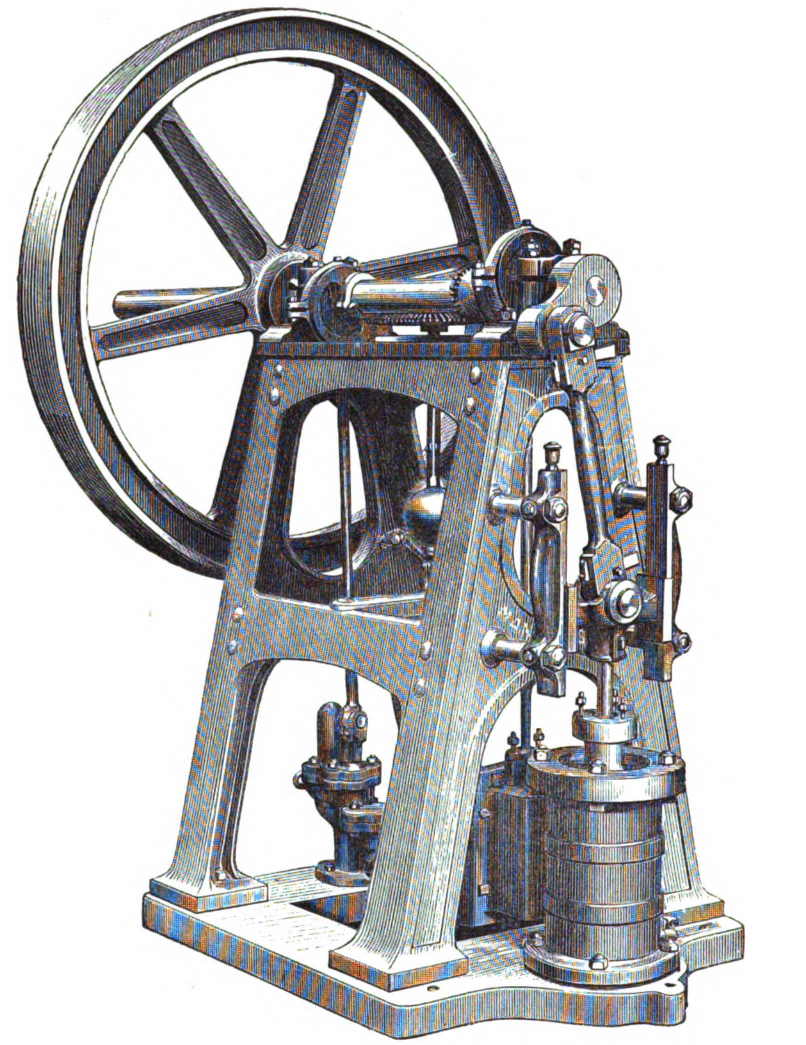
SOUTH KENSINGTON MUSEUM.

ON Tuesday last Professor Huxley gave, at the South Kensington Museum, the first lecture of the course, on the elements of physical science, which is intended for the instruction of women. The course will consist of three parts. The first part Professor Huxley calls physiography, under which rather alarming name many of the audience were no doubt surprised to hear an excessively simple and lucid description of a river basin. The Thames basin was the illustration employed—and the manner in which water is continually circulating between the land, the sea, and the atmosphere. Professor Huxley will proceed in the remainder of this first part to treat in the same broad general manner the most obvious facts and phenomena in the universe, leading up to the second and third parts of the course. These will treat, with somewhat more of detail, of the laws of nature. The second part, by Professor Guthrie, will take up the nature and relations of force in its various forms—the outlines, in fact, of physics and chemistry. In the third part (biology) Professor Oliver will illustrate the phenomena of life (whether physiological or morphological) by the names of elementary botany. The lectures take place on Tuesdays and Fridays, at 11 a.m.

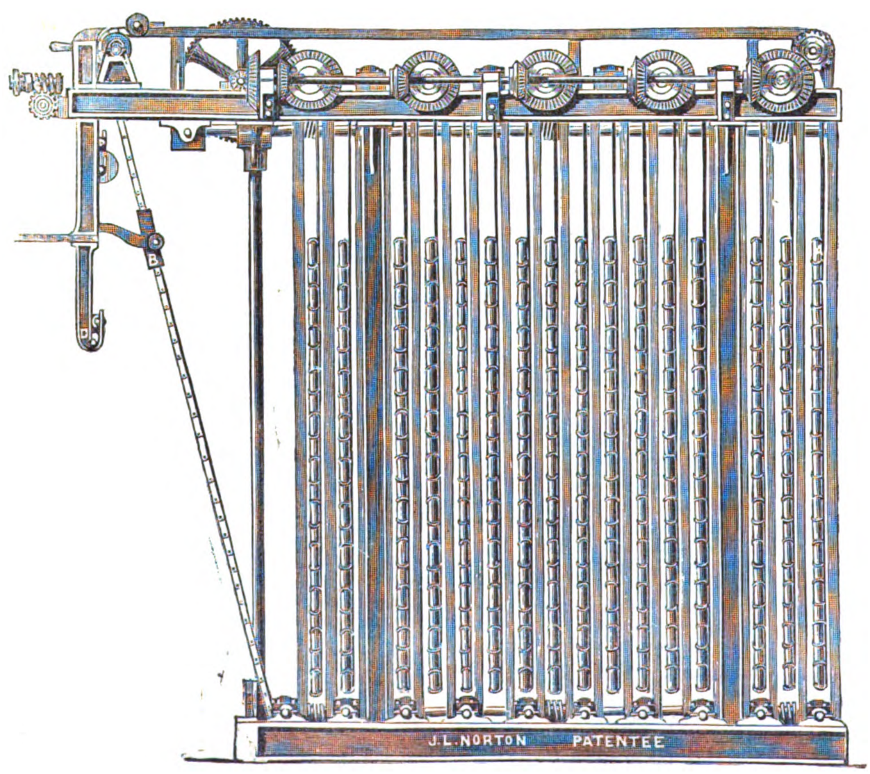
A CORRESPONDENT writes:—This (Saturday) evening, November 6, at about 7 o'clock, two friends and myself were driving along the road adjoining Pen Wood, Highclere, Hants, within a short distance of Lord Carnarvon's park, when we were startled by the appearance of a most brilliant meteor in the south-west. It was of a blue colour, and to our vision seemed to be of the size of a man's head. Unlike many previous meteors, it did not traverse the heavens, but appeared to descend immediately, leaving behind it a long tail of pale blue light, serpent-like in shape. Such was its illuminating power that for a moment or two we might have seen to have picked up a pin in the road. The meteor appeared to descend in the direction of Faccombe.

VERTICAL HIGH-PRESSURE ENGINE.

BY MR. J. L. NORTON.



NORTON'S TENTERING MACHINE.



VERTICAL HIGH-PRESSURE ENGINE AND TENTERING MACHINE.

WE illustrate herewith an improved form of vertical high-pressure engine for general purposes, which is finding favour with users of steam power, and which has been introduced by Mr. J. L. Norton, of 38, Belle Sauvage-yard, Ludgate-Hill, London, well known in connection with the Abyssinian Tube Well. These engines are fitted complete with governors, patent spring equilibrium throttle valves, metallic piston, wrought-iron flywheel shaft, brass pedestal steps, brass eccentric straps, brass connecting rod steps, brass governor wings, &c. The steam joints and jointings of framework are planed and well fitted together, and the workmanship of the engine is finished in a superior style, and to standard gauges. They are strong in build, compact, easy to get at every working part, are extremely easy to fix, requiring but a very trifling foundation. Many of them are working without any foundation stone, being simply bolted to a common boarded floor. They are tested with steam, and proved to work well before they are permitted to leave the works, consequently they may be depended upon for good working as soon as they are bolted down and the steam applied.

A number of these engines are at work in woollen manufactories in connection with Mr. Norton's tentering machines, one of which we also illustrate herewith in side elevation. These machines are used for tentering, stretching, and drying woollen fabrics, and they are in operation both in England and upon the continent, being found very advantageous. They occupy a very small space, a machine to tenter any width of goods from 20in. to 64in. wide, measuring over all about 12ft. 6in. long, 9ft. 6in. wide, and 12ft. high, and being capable of drying at the rate of 1,500 yards of medium cloth per day, and of lighter goods 3,000 to 10,000 yards, according to thickness Goods varying in width from extreme narrows to. 90in. and upwards can be tentered upon the same machine by the introduction of telescopic rollers, which support the cloth its entire width, a desideratum never before accomplished. By a very simple arrangement, velvet or goods with any length of pile can be tentered upon this machine, as the face of the cloth does not come in contact during the drying. The machine is readily set to any width by the man in charge (without leaving his feed-board) by simply moving a handle which regulates the width of the whole apparatus.

INSTITUTION OF MECHANICAL ENGINEERS.

THE general meeting of the members of this Institution was held on Thursday, 4th November, in the Lecture Theatre of the Midland Institute, Birmingham; John Ramsbottom, Esq., Vice-President. in the chair. The Secretary (Mr. W. P. Marshall) having read the minutes of the previous meeting, a number of new members were elected, and the officers of the Institution were nominated by the meeting for the next annual election. The following papers were then read:—

On Well Boring and Pumping Machinery.

BY MR. WILLIAM MATHER.

IN the operation of excavating boreholes for wells and other purposes, the principle adopted and carried out by the writer for all depths of boring has been the use of a rope for working the boring tool in the hole; and this principle obviates the serious expense and delay attending the plan of using rods for working the tool, when great depths of boring have to be executed. In the plan described in the paper the boring tool is worked by a flat hemp rope, which is wound round the drum of a winding engine, and on quitting the drum passes over a large pulley carried in a fork at the top of the piston-rod of a vertical single-acting steam cylinder. The boring tool having been lowered by the winding drum to the bottom of the borehole, the rope is clamped secure at that length; steam is then admitted underneath the piston of the vertical cylinder, and the tool is lifted by the ascent of the piston-rod and pulley; and on arriving at the top of the stroke the exhaust valve is opened for the steam to escape, allowing the piston-rod and carrying pulley to fall freely with the boring tool, which falls with its full weight to the bottom of the borehole. A cushion of steam prevents the piston from striking the bottom of the cylinder, and the steam and exhaust valves are worked by tappets

on a plug-rod; a rapid succession of blows is thus given by the boring tool on the bottom of the borehole.

The boring tool is composed of a number of chisels or cutters, fixed in the cast-iron head at the bottom of the long wrought-iron boring bar, which is guided vertically in the borehole by a couple of collars; and it is made to rotate a little between each blow, so as to strike in a fresh place each time, by means of a simple self-acting arrangement. The lifting shackle at the top of the boring bar is allowed to slide up and down through a short distance on the neck of the boring bar between two fixed collars; the upper face of the lower collar is formed with ratchet-teeth, and the under face of the top collar is formed with similar ratchet-teeth, but set half a turn in advance of the teeth on the lower collar. The intervening boss of the lifting shackle is also formed with corresponding ratchet-teeth on both its upper and lower faces, these teeth being in a line with one another. When the boring tool falls and strikes the blow, the lifting shackle, which during the lifting has been engaged with the ratchet-teeth of the top collar, falls upon those of the bottom collar, and thereby receives a twist backwards through the space of half a tooth; and on commencing to lift again, the shackle rising up against the ratchet-teeth of the top collar receives a further twist backwards through half a tooth. The flat rope is thus twisted backwards to the extent of one tooth of the ratchet, and during the lifting of the tool it untwists itself again, thereby rotating the boring tool forwards through that extent of twist between each successive blow of the tool; and this turning is found to be quite certain and continuous in action during the working of the tool.

When a sufficient quantity of material has been broken up at the bottom of the borehole by the blows of the tool, the working of the percussion cylinder and pulley is stopped, the rope unclamped, and the boring tool wound up with great rapidity by the winding drum. A shell-pump is then lowered down the borehole by the rope, consisting of a long cylindrical shell or barrel, with a clack valve at the bottom opening inwards, and a bucket containing flap valves opening upwards. The rope is attached to the bucket, and when the pump reaches the bottom, the bucket is worked up and down by the rope several times, so as to draw in the broken material through the bottom clack; after which the pump is drawn up again with the material contained in it, and the boring tool again lowered into the hole for continuing the boring. In the event of accidents from breakages or from any of the implements sticking fast in the borehole in rising, grappling tools with hooked claws of suitable shape are employed for laying hold of the obstacle and raising it; or if it cannot be brought up by this means, a solid wrought-iron breaking bar of very great weight is lowered into the hole, and allowed to fall upon the obstacle from a sufficient height to break it up into fragments, which are then raised either by grappling tools or by the shell-pump.

Numerous boreholes have been executed by this plan of boring, both in this country and abroad, for the purpose of obtaining water, and also as trial boreholes for ascertaining the nature of the strata in searching for coal or other minerals, the depth of the borings extending to as much as 1,800ft. The tubing employed, where the borehole is required to be lined, is of cast iron, and is fitted together with turned joints, made with a wrought-iron covering ring, which is let into the thickness of the cast iron and secured by countersunk screws, so as to make the joints perfectly flush both outside and inside. The tubes are forced down the borehole either by screw-jacks or by hydraulic presses, without interfering with the operation of boring, which is carried on simultaneously within the tube. For raising a water supply by pumping from a borehole, the arrangement employed consists in suspending a pump barrel by pipes of the same diameter from the top of the borehole, with two pump buckets working in the barrel, one above the other; the rod of the top bucket is hollow, and is suspended from the horizontal arm of a bell crank lever at the surface, and the rod of the bottom bucket passing up through the hollow rod of the top bucket is suspended from the horizontal arm of a second reversed bell crank lever facing the first lever. The two levers being coupled by their vertical arms and worked by an engine, the two buckets move always in opposite directions; the top bucket in rising lifts the water above it while the bottom bucket is descending, and in the return stroke the bottom bucket ascending delivers the water through the top descending bucket. Although a continuous delivery of water is thus obtained of equal amount in each stroke, a serious shock is occasioned at the beginning of the stroke, in consequence of both buckets stopping and starting simultaneously, causing the whole column of water to be stopped and put into motion again at each stroke; and, as an air vessel for keeping up the motion of the water is inapplicable, a modification of the two bell crank levers has been arranged, which completely answers the purpose. The two levers are centred one above the other, the upper one being inverted; and the vertical arms are slotted, and are both driven by the same crank pin working in the slots; in the revolution of the crank the dead point of one of the levers is thus passed before that of the other is reached, so that the first bucket is started into motion again at the end of its stroke before the second comes to rest. By this means the water is maintained continuously in motion with entire freedom from concussion. Specimens were exhibited of the boring tool and shell pump employed in excavating boreholes, together with a large collection of cores raised from various boreholes, showing the nature of the strata passed through.

Machine for Shaping Nuts.

BY MR. W. F. BATHO.

This machine is for the purpose of shaping the external faces of hexagonal nuts, and consists of six horizontal revolving cutters, arranged radially at the same level, and driven by a single bevel wheel gearing into the six bevel pinions that carry the cutter spindles. The cutters are so fixed in their spindles that when the cutting edges of one tool are horizontal those of the adjoining ones are vertical, and they consequently miss one another in revolving, and can thus operate on work the faces of which are narrower than the breadth of the cutters; by this means the contiguous faces of the hexagonal nuts are all shaped simultaneously by the revolving cutters. The nuts to be shaped are threaded upon a vertical centre mandrel, to which a vertical feed motion is given, traversing the nuts upwards or downwards in the middle of the revolving cutters; and the shaping of the six faces of the whole row of nuts on the mandrel is completed in a single traverse of the machine. The cutters are made with the cutting portions limited to the two sides of the tool, acting like two independent cutters in an ordinary fly-cutter, so that the cutting action is similar to that of a roughing-out tool in a lathe or planing machine; with this shape the wear upon the cutters is so small that each lasts a long time before it is ground down so low as to require renewal. Different sizes of cutters are used according to the size of the work to be shaped; and each cutter is set up by hand-wheels to the required distance from the centre of the machine. The vertical feed motion is obtained by a screw and worm-wheel driven by bevel gearing, with a reversing clutch which is thrown out of gear by a tappet at each extremity of the vertical traverse. A working specimen was exhibited of the machine, together with samples of nuts shaped by it of various sizes, and of other work with a different number of sides, made by using a different number of cutters.

On Le Chatelier's Plan of Using Counter-Pressure Steam as a Brake in Locomotive Engines.

BY MR. C. WILLIAM SIEMENS.

In ordinary locomotive engines, when the valve gear is reversed while running forwards, for obtaining in an emergency the retarding effect of the full boiler pressure opposing the motion of the pistons, the reversed working cannot be continued longer than a few minutes without serious injury, owing to the heating of the cylinders and the cutting of the rubbing surfaces from want of lubrication; the cylinders act as pumps in the reversed working, drawing in the heated gases from the smokebox, and forcing them into the boiler. The object of the present plan is to enable locomotives, in taking trains down inclines, to be worked continuously for any length of time with the valve gear reversed, so as to obtain the advantage of the counter-pressure steam as a retarding power instead of the train brakes, without involving the objections hitherto preventing the use of continuous reversed working.

In the regular working of locomotives, not reversed, the piston, in its forward stroke, is propelled by the full pressure of steam from the boiler, until the steam is cut off by the slide valve; after which, the propelling power is continued through the remainder of the stroke by the steam expanding in the cylinder. But in the reversed working, the distribution of steam is effected by the slide valve in the inverse order and on the opposite side of the piston, while the motion of the piston and driving wheels still continues in the same direction as previously; in the first portion of the stroke, therefore, the cylinder is open to the exhaust on the front side of the piston; but, in the latter portion, the steam at full boiler pressure is admitted, and opposes the forward motion of the piston. In the return stroke, the front of the piston in ordinary working is in communication with the exhaust until nearly the end of the stroke; but in the reversed working, it is to the back of the piston that the exhaust is open, and the piston accordingly draws in the heated gases from the smokebox at atmospheric pressure; and in the next forward stroke, the contents of the cylinder are compressed as soon as the exhaust port closes, and forced by the piston into the boiler against the full pressure of steam. The latter portion of each stroke of the piston is thus made against the full boiler pressure, which resists the motion of the piston, and consequently acts as a powerful retarding force to check the rotation of the wheels in the direction of running.

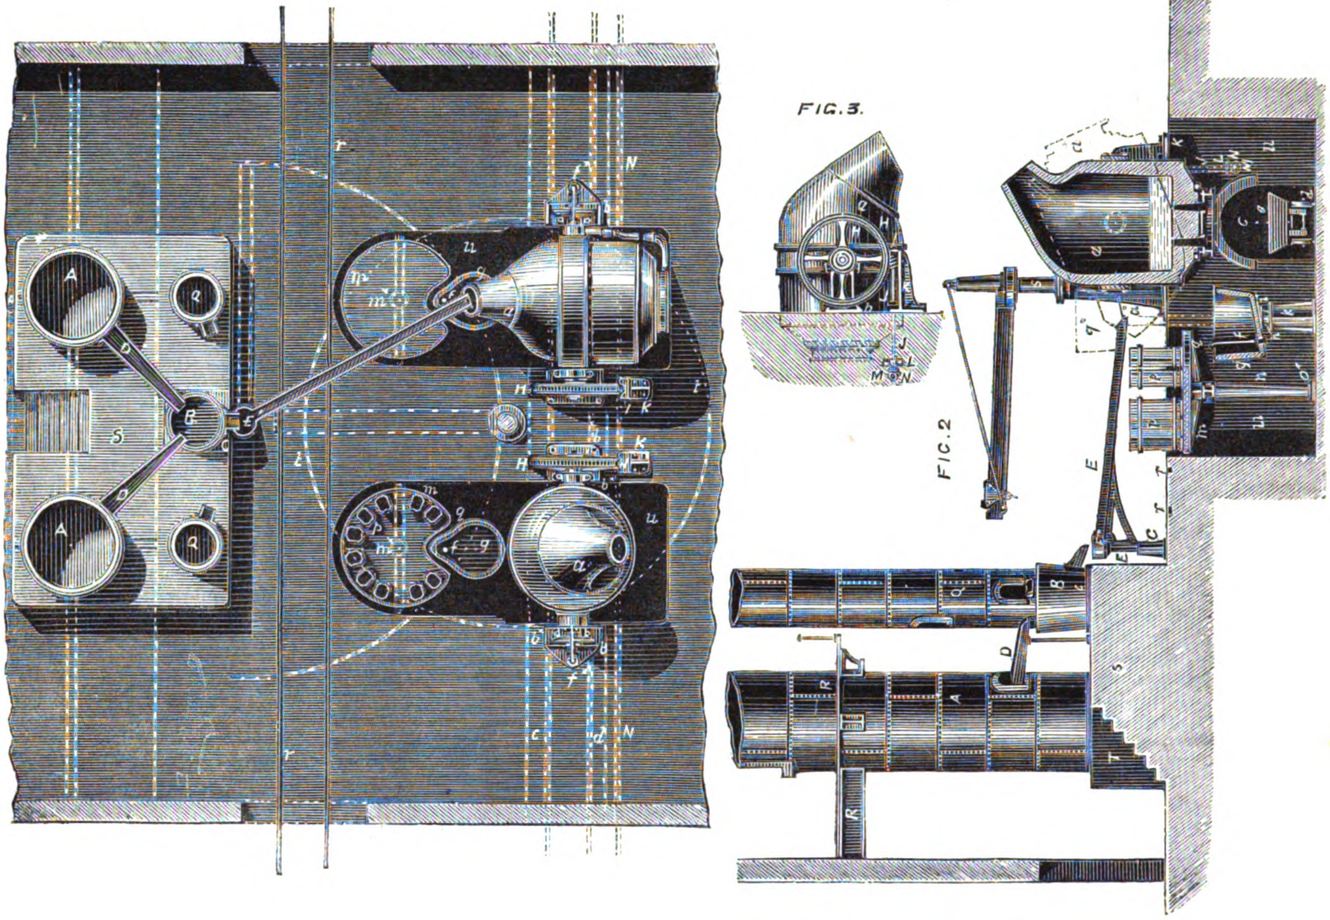
The simple and efficient plan designed and carried out by M. Le Chatelier for counter-pressure working consists in introducing a small jet of hot water from the boiler into the base of the blast-pipe or the exhaust port of the cylinder; this jet being discharged at boiler pressure into the atmospheric pressure of the exhaust passages, the greater portion of the water instantly flashes into steam at atmospheric pressure, and, instead of the heated gases from the smoke-box, a moist vapour or fog is now drawn into the cylinder behind the piston. The rubbing surfaces are thus maintained constantly lubricated by the presence of saturated steam, and all heating or cutting is entirely prevented. The jet of water is regulated so as to be always slightly in excess of the precise quantity required, the object being to prevent the possibility of drawing in any of the heated gases from the smokebox; and the constant escape of a slight cloud of steam from the chimney affords an indication to the driver of the sufficiency of the jet. Mixed jets of hot water and steam in various proportions have also been employed in particular cases of working. The use of the counter-pressure working has the important advantage of rendering the great weight of the engine available as brake power; and as the amount of retarding power obtained from the counter-pressure steam against the pistons when running reversed is less than the propelling power of the steam in ordinary working, the engine wheels are not skidded upon the rails; but a steady retarding force is continuously applied to them within the limit of their adhesion. The wear of rails and tyres that is caused by the friction of the train wheels when skidded by the ordinary brakes, and the consequent injury to the wheels by wearing flat places in their circumference, are avoided to the extent that the counter-pressure steam is used as a brake on the engine; and the practical working of the counter-pressure plan has been found so satisfactory, that its use has even been carried so far in many cases as to supersede the employment of the train brakes, not only in descending inclines but also in stopping and shunting at stations. In shunting, the steam regulator is left constantly open, and the motion of the engine is controlled entirely by the reversing handle. The employment of the counter-pressure working has now been extensively adopted in France, Spain, and other countries, as many as fourteen hundred locomotives being regularly worked on this plan on the Paris and Lyons Railway alone, both in descending inclines and in stopping and shunting at stations; and in all cases its adoption has been attended with complete success.

The Royal Seamen and Marines' Orphan School and Female Orphan Home, Portsea, is an institution which has claims to national support. We are glad to learn that our seamen and marines are taking an increased amount of interest in its welfare, and recently the reading-room club of the "Pallas," armour-plated screw corvette, on paying off, sent by the Rev. F. Davies, the chaplain, £2 10s. to the institution, and £2 to the National Lifeboat Institution. The serjeants of the Royal Marine Artillery, stationed at Eastney, Southport, have sent to the Seamen and Marines' Orphan School £4 12s., being the proceeds of an amateur dramatic performance. We may mention that the institution is in want of funds, and that subscriptions will be received by the Rev. E. S. Phelps, chaplain of Portsmouth Dockyard, honorary secretary.

APPARATUS FOR MANUFACTURING STEEL AND IRON.

BY MR. BESSEMER.

FIG. 1. FIG. 3. FIG. 2.



MANUFACTURE OF CAST STEEL AND MALLEABLE IRON.

THE production of ingots of cast steel or malleable iron from pig or other carburet of iron by the forcing of atmospheric air upward through the molten metal, and now generally known as the Bessemer process, consists of several distinct operations carried on in succession. The most important of these operations consist in melting the pig metal, transferring it in the molten state to the converting vessel, blowing air through it, and converting it into a malleable metal, mixing the metal so converted with a certain quantity of fluid manganesian pig iron, pouring the mixed metals into a casting ladle, and running it from thence through a valve into moulds, and the removal therefrom of the ingots when solidified.

It is essential to the economic performance of these successive operations that the several kinds of apparatus employed should occupy such positions in reference to each other that no unnecessary time should be employed in passing the metal from one to the other, that the metal in its fluid state should not be unnecessarily cooled by exposing it to radiation in open gutters of great length, and that the motion of the several parts of the apparatus should be capable of being effected with ease and certainty, with a view to economise time, save labour, retain heat, and conduct the process with safety. These objects are sought to be accomplished by the apparatus we are about to describe, and which has recently been patented by Mr. Bessemer. In this arrangement the first cost of the combined apparatus will be much reduced as compared with the cost of the apparatus now generally employed in the manufacture of Bessemer steel and iron, while the size and cost of the building will also be much reduced.

The arrangement and construction of the converting apparatus is represented in plan at fig. 1, and in vertical section at fig. 2 of our engraving; a side elevation of the converting vessel showing the gearing for giving it rotation is shown at fig. 3. *a a* represent two converting vessels so placed that their respective axes are in a straight line, in which position any required number may be placed along one side of the "converting house;" the axes of the vessels are supported on massive castings *b*, the upper parts of which are formed into plummer blocks *b** for the axes to turn in. Each of the converters *a* stands over a separate pit *u*, through which an arched passage *c* leads to the outer sides of the building. In this passage are fixed the rails *d*, on which an iron truck *e* may be moved beneath any number of vessels placed in a line and receive from them the slags, cinders, or other debris, and convey it out of the converting house. The pipe and usual valve arrangement for the supply of air to the converter is shown at *f**. In front of each vessel is a casting ladle *g* mounted on the top of a vertical slide or ram *h*, the upper part of the slide having a table *i* for the ladle to stand upon. The ram has a vertical movement given it by means of hydrostatic pressure acting in the cylinder *k* in which the ram works. The casting ladle so mounted will be lowered as the metal from the converter is poured into it, after which it will be raised again so high that its under side will rise above the top of the moulds, as shown by dots at *g**; the moulds are brought successively under it by turning the table *m*, and are filled by means of the valve arrangement *f* now generally employed in casting Bessemer steel.

In front of the casting ladle is mounted a circular bed or table *m* on a vertical spindle *n* moving in a bearing *o* and foot step *o**; the upper surface of the table is protected with brick or sand *m**. On this table the moulds *p* are placed in a concentric circle; a hollow or indented part *q* is formed on one side of the table to allow the casting ladle *g* to rise up past it; the table is rotated, and thus each mould is quickly and with little force brought under the ladle to be filled. Against the side walls are fixed small cranes to lift off the ingot moulds and ingots from the revolving tables and transfer them to trucks moving on the rails *r* laid in a line parallel to the line of converting vessels; or in lieu of the wall cranes Mr. Bessemer uses an hydraulic crane such as is generally known as an ingot crane, and represented at *s*, figs. 1 and 2, and placed between each pair of converting vessels, the range of the gib shown by dots *t* being such that the top of the converter or the tuyere box may be removed by it on to a truck moving on the rails *r*, and be carried out of the converting house.

Both when using the line of rails or the circular table to move the moulds Mr. Bessemer prefers to place the cupola melting furnaces A A before the converting vessels, so that when the vessels are turned down, as shown by dots at *a**, fig. 2, to receive a charge of molten iron the mouth of the vessel shall approach nearer to the cupola A. When two converting vessels are used Mr. Bessemer employs two large cupolas, as shown at A A, but when a greater number than two converting vessels are used in a line the arrangement and number of cupola furnaces is varied to suit the requirements of the manufacturer and the hours of working. The cupola furnaces may be of the ordinary kind used by founders, but Ireland's upper tuyere furnace or Woodward's steam jet cupola are preferred. In either case in a line between the cupolas, but preferably nearer to the converting vessels, a ladle or receiver B is mounted on a weighing machine C with a short spout D from each cupola leading into it, so that the charge of iron to be converted is first run into the receiver B and weighed. Beneath the tap hole of the receiver is placed the enlarged end E* of a swinging gutter E, by which the iron may be run (above the level of the turntable or line of moulds and trucks) into the mouth of the converter. The movable gutter or spout D is supported in a vertical spindle F, which is retained in position by a pedestal G bolted to the foundation. The spout E is capable of supplying both converting vessels, and when not in use may be moved out of the way by turning it in a direction parallel to the rails *r*. By this arrangement each of the cupolas may be employed to supply either of the converters, the exact quantity of

MACHINERY FOR WELDING BOILER PLATES.

BY MESSRS. BEELEY AND HANSON.

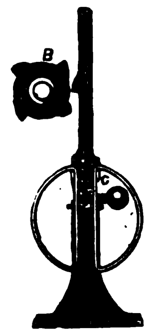

FIG. 6.

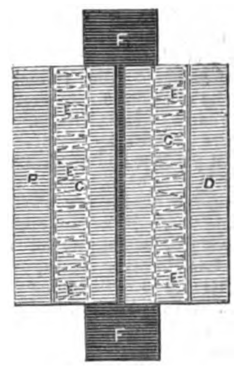


metal employed being ascertained by weighing it in the receiver B before running it into the converter.

At fig. 3 a large worm wheel H is shown on the axes of the converting vessel; a worm I on the vertical shaft J gears into the worm wheel, and is supported by the frame K bolted to the foundation. A bevelled wheel L is keyed on to the lower end of the shaft J, and is geared into another bevelled wheel M on the horizontal shaft N; this shaft extends entirely across the building, and is connected with an engine having a reversing valve gear, so that the shaft N may be put in motion, reversed, or stopped when required by a workman so placed that he can see the pouring out of the molten metal into the ladle, and be enabled to regulate the motion of the converter. A clutch is also provided for the purpose of disengaging the bevelled wheel M, when the vessel to which it gives motion is required to be at rest. When two converting vessels are grouped as described two small cupola furnaces Q Q are used for melting the magnesian carburet of iron or spiegeleisen. These may be placed near the weighing ladle, as shown, and the iron from them be run into the vessel or casting ladle along the gutters before named. But Mr. Bessemer prefers to tap these small furnaces into a swing or travelling ladle, where the iron may be weighed, and be thus transferred to the converter or casting ladle without being cooled or wasted by passing along a gutter. An upper floor is formed on girders, as shown at R, fig. 2, at that part of the converting house where the cupola furnaces are situated, on to which floor the metal and fuel are hoisted by a lift. The cupola furnaces A and Q are erected on a raised bed of masonry S in order that the workman may have a platform to stand on when tapping the furnaces; the steps T give access to this raised platform.

The trunnion bands generally employed in converting vessels are of forged iron, and from the difficulty of making them are very expensive; Mr. Bessemer therefore replaces them in some cases by employing a hoop of cast iron with the trunnions and air passages formed therein. In this case he uses rolled angle irons to embrace the cast-iron hoop, and by passing bolts entirely through the cast iron and rolled angles the several parts of the cast-iron hoop would be supported in case of accidental fracture.

WELDING PLATES AND TUBES FOR BOILERS.

MR. THOMAS BEELEY, of Hyde Junction Iron Works, Chester, and Mr. David Hanson, of Dukinfield, have lately patented some useful improvements in boiler making. In the first place, their invention consists in a machine by which the blows for welding the seams are struck, instead of employing a number of labourers for this purpose as at present. The machine consists of a number of stampers or strikers, which are arranged side by side in a row. These strikers are so arranged that they may be raised to a certain definite height, and then be allowed to fall by their own weight. Below this row of strikers is the anvil, which may be similar in shape to that now in use for this purpose, or curved to the requisite form for welding or flanging.

A machine of this description is shown in the accompanying engraving, at figs. 1, 2, 3, and 4, fig. 1 being a side view; fig. 2, a front view; fig. 3, a plan; and fig. 4, a sectional plan taken on line a b in fig. 1. A A are the stampers, upon which are formed the projections B B; C is the shaft which carries a number of circular plates D D, upon which are formed the cams E E. These plates are shown in section in fig. 4. The stampers A A slide in guides F F, and the force of the blow may be increased by the springs G G. The machine is carried by side frames H H. I is the anvil, and K represents a plate being welded. This is the most convenient method of putting this part of the invention into practice, although other methods may be adopted. The shape of the face of the stampers corresponds to the shape of the plates to be welded, being straight for flat plates and curved for curved plates, and there are a sufficient number of them in the machine to weld the longest plate used in the works. Each stamper is provided with a catch, by means of which it may be kept out of gear with the revolving shaft, and thus be prevented from striking, as in some plates there will probably be a portion which will not require to be welded. The simplest form of catch for this purpose consists of a key placed in a slot in the stamper, as shown at I, fig. 1.

In the next place, the present invention consists in an improved form of furnace for heating the plates intended to be welded by the apparatus we have described. The furnace is made of sufficient length for the longest plates used, and is constructed of iron plates, the mouth being narrowed along its whole length. On each side and next to the furnace is a water chamber, which is supplied in the usual way, and next to each of these water chambers is an air chamber, which serves to distribute the blast. The water chambers and air chambers extend the whole length of the furnace, and a row of tuyeres proceed from each of the air chambers through the water chambers into the furnace. These tuyeres are arranged so that the nozzles of one row do not come directly opposite, but half way between those of the other row. Fig. 5 is a cross section, and fig. 6 is a plan of a furnace constructed according to this part of the invention. A is the furnace with the narrow mouth or opening B; C C are the water chambers, and D D the air chambers; E E are the tuyeres passing from the air chambers through the water chambers to the furnace A. This furnace is not charged with fuel on the top, but at the ends, that is, at F F, fig. 6, the ends being kept closed by a charge of black fuel. The advantage of this arrangement is that it will be unnecessary to blacken that portion of the furnace which heats the plates when feeding the furnace with fresh fuel. This furnace is provided with dampers underneath, as shown at G, fig. 5.

Messrs. Beeley and Hanton's improvements further consist in a novel form of furnace for heating the ends of the cross tubes and the corresponding

openings in the flues, and the cylindrical portions of flues or boilers required to be welded together. The furnace is made of an annular form, with the tuyeres arranged in a radial direction around it, the tuyeres passing through the water chamber, as before described. Fig. 7 is a plan of this furnace. The centre A is made of firebrick; B is the annular furnace; C is the water chamber; D is the air chamber, from which the tuyeres E E pass to the furnace.

A simple apparatus for welding the cross tubes into the flues of boilers is also included in the present invention. This consists of a rising and falling striker, the face of which is shaped to suit the corner formed by the junction of the flue and the cross tube. In conjunction with this striker is an anvil which has been previously patented by Mr. Beeley. This arrangement is illustrated in fig. 8. A is the rising and falling striker, to which the necessary motion may be imparted by the revolving shaft B; C is the anvil. This apparatus has been at work for some time, and is found very effective and economical.

THE ROYAL POLYTECHNIC INSTITUTION.

A VERY interesting addition has recently been made to the numerous attractions offered by the Royal Polytechnic Institution to the public. This consists in an exhibition of imperial relics of the unfortunate Maximilian Empire, and a number of Mexican curiosities. Chief in prominence amongst the former are two life-size portraits of the late Emperor Maximilian and his wife, the Empress Carlotta. These rare gems of art were painted by Santiago Rebull, the great portrait painter, and professor of the Academy of St. Carlo, city of Mexico. There is also a large oil painting portraying the Emperor's entrance into Mexico. Next we come upon a miniature sarcophagus, containing an exact representation of the late Emperor as he appeared when embalmed and passed into the keeping of Admiral Toghatoff, for removal to Austria, on the 12th of November, 1867. His body is clothed in the citizen dress. The sarcophagus is made of the same wood, and by the same mechanic who made the original. Another miniature sarcophagus contains a representation of the dead body of the Emperor, showing the six points at which the bullets entered his body. In addition to these is a numerous collection of interesting articles, including hats once worn by Maximilian, the immense Mexican sombrero which he had on when captured, uniform, coats, hats, with the Empress Carlotta's riding hat, autographs, glass ware, &c., all of which are full of mournful interest to the public, who will well remember the sad fate of the unfortunate Emperor, and the affliction which has darkened the days of his devoted wife.

Amongst the Mexican curiosities are several relics of the dark ages, when the Spanish Inquisition annually numbered its victims by thousands. There is a manuscript work in the handwriting of the Junta, City of Mexico, bearing date 1595, and containing the records of the trials of many of the victims of the Inquisition, together with the horrible sentences pronounced against them. A remarkably fine mummy also calls for attention, being in an extraordinarily good state of preservation. That this was one of the victims of the cruelties then perpetrated there can be no doubt, as the body is somewhat distorted and indented by ligatures. Altogether this collection will well repay a visit, and must prove a great attraction to the Polytechnic Institution.

MINERALS AND METALS IN 1868.

THE following facts and figures relating to the produce of various minerals and metals in the year 1868 are compiled from reports and returns upon the matters in question, and will be found both interesting and useful. They include gold, silver, lead, tin, zinc, coal, clays and china stone, and salt. We first turn to the present aspect of gold in Australia, and we find that the imports of Australasian gold into the United Kingdom in the eight months ending August 31 this year amounted to £5,151,549, as compared with £4,361,243 in the corresponding period of 1868, and £3,277,613 in the corresponding period of 1867. The amount of the gold brought down by escort in the province of Otago, New Zealand, in the first six months of this year was 71,214oz., as compared with 71,618oz. in the first six months of 1868. It is stated that there is a prospect of a valuable goldfield being found in the Marewhenua district, about forty miles from Oamaru, in the province of Otago. Mr. Warden Robinson has been directed to visit the workings, and report upon them to the Provincial Government. About 100 men were at work in the locality at the last dates. some good specimens of auriferous quartz had been found, and, as the district adjoins that of Mount Ida, it is expected that a similar formation will be found to exist over a wide extent of country. There are now eighty-seven companies formed in connection with the gold mining of the Thames fields, in the province of Auckland, New Zealand. These eighty-seven companies had raised between them capital to the amount of £1,270,201. A large demand for skilled mining labour is stated to prevail on the Thames fields, which are extraordinarily rich.

From another return, it appears that the average number of gold miners employed in Victoria in 1868 was 63,181, being a decrease of 2,676 upon the corresponding average for 1867. The average earnings of each man last year were £104 18s. 8d., as compared with £87 1s. 7d. in 1867. There are 2,651 ascertained quartz reefs, and 886,228 tons of quartz were crushed in 1868. The average yield of gold was something over half an ounce to the ton, while the cost of crushing ranged from 2s. 6d. to £1 10s. per ton. The extent of auriferous land opened up by gold miners in Victoria is 882 square miles, and the value of the machinery and mining plant employed was estimated last year at £2,150,432. The total area of the land held as claims was 100,942 acres, of which nearly one-third was last year lying idle; the computed value of the whole of the claims was, last year, £8,869,504. Twelve new goldfields were discovered last year, and 329 new companies, with a nominal capital of £3,719,198, were registered during 1868. The aggregate value of the gold exported from Victoria to the close of 1868 was £147,342,767. The total quantity of gold exported from Queensland in the six months ending June 3 was 67,080oz., or at the rate of 11,180oz. per month. If the exports continue at the same rate for the remainder of the year, they will amount in value to upwards of £500,000 for the whole of 1869. The exports for the second quarter of this year showed, however, the slight decline of 657oz.

Turning next to silver and lead, we find that the quantity of lead ore raised and sold in the United Kingdom was but 78,944 tons in 1848, but since 1850 it has almost always ranged between 90,000 tons and 100,000 tons in the year; in 1868 it was 95,236 tons, of the value of £1,150,768, the price at the Holywell sales averaging £12 1s. 8d. or about 16s. lower than in 1867. The quantity of load obtained from the ore was 53,373 tons in 1848, but in 1868 it reached 71,017 tons, of the value of £1,378,404. In 1848 it took 147·9 tons of ore to make 100 tons of lead, but the required quantity has been reduced since then, and in 1868 it took only 134·1 tons, or, in other terms, there were 74·568 tons of lead in 100 tons of ore. The quantity of silver produced was but 496,475oz. in 1853; it had risen to 569,345oz. in 1858, and reached 841,328oz. in 1868, of the value of £231,365. In 1853 there were obtained 8·143oz. of silver from the ton of lead; in 1858, 8·336oz.; in 1868, 11·846oz. From the ore produce of lead mines in Cornwall there were obtained in 1868 6,310 tons of lead and 303,033oz. of silver; from Durham and Northumberland, 17,805 tons of lead and 81,447oz. of silver; from Yorkshire, 5,655 tons of load and 2,500oz. of silver; from Derbyshire, 4,396 tons of lead and 1,150oz. of silver; from Cumberland, 4,097 tons of lead and 33,057oz. of silver; from Shropshire, 3,823 tons of lead; from Westmoreland, 1,388 tons of lead and 21,314oz. of silver; from Devonshire, 1,141 tons of lead and 39,865oz. of silver. In Wales, Denbighshire in 1868 supplied 6,382 tons of lead and 33,370oz. of silver; Cardiganshire, 5,414 tons of lead and 67,502oz. of silver; Flintshire, 3,255 tons of lead and 29,808oz. of silver; Montgomeryshire, 3,050 tons of lead and 19,546oz. of silver. The supply in Scotland is chiefly from Dumfriesshire. In Ireland, Wicklow produced 1,324 tons of lead and 13,245oz. of silver; Tipperary, 31 tons of lead and 1,127oz. of silver; Waterford, 154 tons of lead; and Louth, 53 tons. The totals for Scotland in 1868 were 2,437 tons of load ore, 1,812 tons of lead, 8,201oz. of silver; all these are smaller quantities than in the preceding year. The totals for Ireland in 1868 are 2,089 tons of ore, 1,562 tons of lead, 14,372oz. of silver; all these are larger quantities than in the preceding year, but there are returns from more mines in 1868. The Isle of Man supplied in 1868 4,290 tons of lead ore, 3,089 tons of lead, and 178,718oz. of silver.

With regard to tin and the tin-plate trade, we first note that the produce of the tin mines and streams of Cornwall and Devonshire in the year 1868, according to returns obtained from the smelters, was 13,953 tons of tin ore (black tin), of the value of £770,205, an increase of 304 tons over the quantity in 1867; and the quantity of metallic tin (white tin) obtained was 9,300 tons, of the value of £901,400, an increase of 600 tons over the quantity in 1867. The average price of tin ore in 1868, as deduced from all the sales, was £55 4s. per ton. This is considerably lower than the average for the ten years 1856—65, but higher than the average prices of the years 1866 and 1867, which were £48 10s. 9d. and £50 18s. respectively. The mean price of metallic tin in the London market in 1868 was £98 per ton for English blocks, £95 13s. 4d. for Banca, £93 16s. for Straits; all of them materially higher prices than in 1867. Dues were paid to the Stannary Court in 1868 on 11,584 tons of tin ore —viz., in Cornwall, on 2,276 tons from mines in the western district, on 7,820 tons in the west central district, on 780 tons in the east central district, on 453 tons in the eastern district, and on 201 tons from sundry mines selling ore in the stone; and, in Devonshire, on 54 tons. The total is above that of 1867, but below that of any of the five years preceding 1867. The Dolcoath mine, in the west central district of Cornwall, continues at the head of the returns, showing in 1868 a production of 984 tons of tin ore, of the value of £55,847.

The position of the tin-plate trade has, we regret to say, been exceedingly unsatisfactory for some time past, the demand having fallen off to a great extent, and the prices realised are quite unremunerative. Last year, and for the first three or four months of the present year, such an enormous quantity of plates was exported to the United States that the markets there became glutted, and the result was that plates were selling at New York at lower prices than at Liverpool. As might be naturally expected, the extreme depression has brought about heavy failures in the trade, which have necessitated the stoppage of several works, and it is generally agreed that there must be a reduction of make at all the tin-plate establishments before stock can be sufficiently reduced to command higher quotations. The Abertillery works, which have been at a standstill in consequence of the failure of the late proprietor, have been sold at less than one-half the purchase-money thirteen years ago, which is a proof of the unfavourable position of the trade just at present. There are strong hopes, however, that with the reduced make and increased American purchases the next spring will witness some degree of revival in the demand.

The returns obtained from the zinc mines of the United Kingdom show a production in the year 1863 of 12,782 tons of zinc ores, principally sulphide of zinc (black jack), the value being estimated at about £39,192. The number of mines was 35—18 in England, 15 in Wales, 1 in Ireland, 1 in the Isle of Man. In England and Wales the chief production was from three counties; 3,350 tons from Denbighshire, 2,858 tons from Flintshire, 2,061 tons from Cornwall. 3,278 tons were produced in the Isle of Man. The production of metallic zinc was about 3,713 tons, of the value of £75,436. All these figures are lower than those for the preceding year, 1867. Prices were lower in 1868 than in 1867 in the London market, the mean price of spelter falling from £21 6s. in 1867 to £20 6s. 4d. in 1868, and the mean price of zinc (in sheets) from £27 7s. 6d. to £25 13s. 4d. per ton.

Our "black diamonds" next demand a notice, and here we may observe that the 103,141,157 tons of coal produced in the United Kingdom in 1868 were raised from 2,922 collieries. The quantity was above 1,300,000 tons less than in 1867, a result attributable to the long-continued commercial depression. In Durham and Northumberland 24,394,167 tons were raised in 1868, being 473,277 tons less than in 1867. In Cumberland 1,378,026 tons were raised in 1868, a decrease of 134,488 tons. In Yorkshire 9,740,510 tons, a decrease of 103,065 tons. In Derbyshire 4,957,879 tons, an increase of 407,329 tons. In Nottinghamshire 1,508,439 tons, a decrease of 66,561 tons. In Leicestershire 608,088 tons, a decrease of 541,912 tons. In Warwickshire 624,859 tons, a decrease of 255,991 tons. In Staffordshire and Worcestershire 12,294,780 tons, a decrease of 231,774 tons. In Lancashire 12,800,500 tons, a decrease of 41,000 tons. In Cheshire 837,500 tons, an increase of 2,500 tons.

In Shropshire 1,495,500 tons, a decrease of 63,000 tons. In Gloucestershire and Somerset 1,969,000 tons, a decrease of 6,000 tons. In Monmouthshire 4,2[illegible]0,500 tons, a decrease of 319,000 tons. In South Wales 8,959,500 tons, a decrease of 132,800 tons. In North Wales 2,385,000 tons, an increase of 13,750 tons. In Scotland 14,709,959 tons, an increase of 584,016 tons. In Ireland 126,950 tons, an increase of 1,950 tons. The mean price of Newcastle coal, Wallsend, in the London market in 1868, was 15s. 9d. per ton, being 2s. 6d. less than in 1867.

The returns stating the production of the more important clays and china stone in this country in the year 1868 show that Cornwall produced 100,000 tons of porcelain clay, of the value of £91,666; 29,000 tons of china stone, of the value of £23,200; and 1,479 tons of fireclay, of the value of £554. The first two items show smaller quantities than in 1867. Devonshire produced in 1868 12,000 tons of porcelain clay, of the value of £9,600, and 45,000 tons of Teignmouth clay, of the value of £20,250. The last item shows not quite so large a quantity as in 1867. In Dorsetshire 150,000 tons of pottery and other clays, of the value of £3,750, were obtained in 1868. There were also produced in Staffordshire, Yorkshire, Derbyshire, &c., 675,000 tons of fireclays, of the value of £168,750. These items amount to 1,012,479 tons of fine and fire clays, of the value of £317,770. This is not so large a return as that of 1867. A list of porcelain and other clay works working in 1868, compiled by Mr. Robert Hunt, the keeper of mining records, shows 90 in Cornwall; in Devonshire 5 producing porcelain clay and 4 Teignmouth clay, and there were also 11 producing Poole clay, and 16 in Staffordshire producing Stourbridge clay.

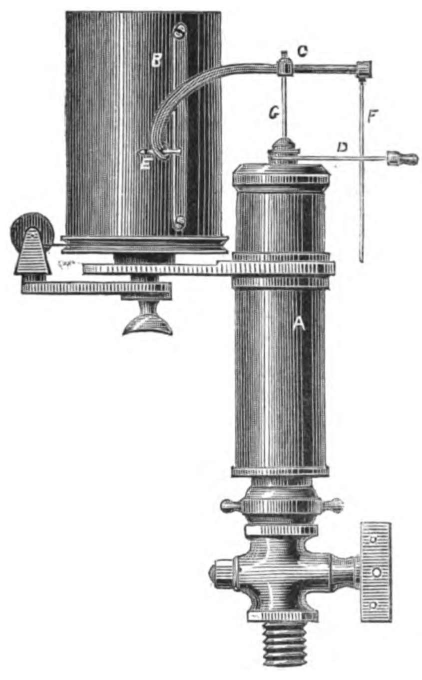
Finally, with regard to salt we find that the quantity made in Cheshire in the year 1868 is stated at 1,250,000 tons, the same quantity as that reported in the preceding year; but the quantities sent down the River Weaver show a large increase, the quantity of rock salt sent down with the year ending with March, 1869, reaching 58,696 tons of 26cwt., and of white salt, 901,566 tons, making a total of 960,262 tons. The returns of the quantity of salt made in Worcestershire show 240,000 tons in 1868—namely, 115,000 tons at Droitwich, and 125,000 tons at Stoke Prior. In Ireland the quantity in 1868 was 23,840 tons, an increase of 4,151 tons over the preceding year. The export of salt from the United Kingdom continues to increase. In 1865 it was 579,050 tons; in 1866, 601,440 tons; in 1867, 724,333 tons; in 1868, 797,502 tons. The declared value of the salt exported in 1868 was £485,537. The increase is chiefly in the exports to India and to Russia.

DIRECT-ACTING STEAM ENGINE INDICATORS.

MESSRS. J. A. and J. HOPKINSON, of Huddersfield, have patented some improvements in direct-acting steam engine indicators, which consist in making the indicator with a detached revolving barrel, and dispensing with the slides in which the pencil holder usually works. For this purpose an arm or pencil holder is fixed upon the top of the ordinary piston rod of the indicator, which arm turns on a swivel centre. At a lower point there is fixed a swivel guiding arm, which is so formed as to admit of a drop guiding rod passing through it, so that, by turning the swivel arm, the pencil can be brought upon the paper which is usually fixed on the revolving barrel, thereby facilitating the taking of diagrams. This arrangement not only dispenses with the ordinary slides, but also with joints, and prevents unnecessary friction, together with the liability to derangement, and allows other improvements to be carried out.

In our engraving, E is the pencil at the end of the swivel arm C, a part of which is turned down to a collar and fits on the piston rod G, being held by a nut on the upper side. D is a horizontal arm working from the cap cover of the barrel A, and acted upon as required by the hand of the attendant. In this arm is formed a hole, through which the drop guiding rod F slides. It will be seen from this connection that any upward or downward motion of the piston rod will be imparted to the swivel arm C, and that, by directing this motion through the medium of the arm D upon the barrel B, the pencil may be applied or withdrawn with the utmost facility, and indications may be registered as required.

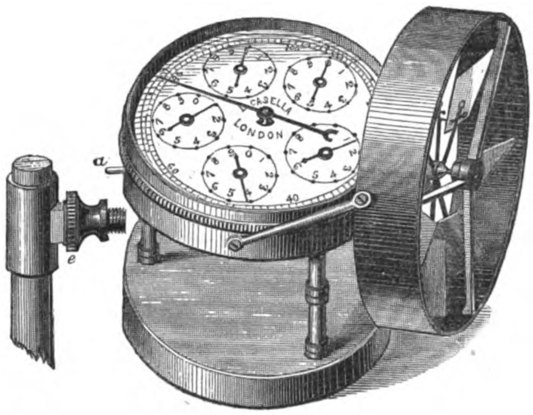
The internal arrangement of piston and spring is similar to the usual description of indicator, and does not therefore need to be described. The novelty in this instrument consists in the lightness



of the arm, and the important feature of having only one joint, thereby securing increased steadiness and firmness at the point of the pencil.

AIR METER.

BY MR. CASELLA.



AIR METER.

THE object of the little instrument illustrated herewith is to give correct means of measuring the velocity of currents of air passing through coal and other mines, and the ventilating spaces of hospitals and other public buildings. It was first constructed for Dr. Parkes, F.R.S., of the Royal Victoria Hospital, Netley, for measuring the state of ventilation in that large military establishment, and declared to be the most perfect instrument of the kind in use. Since then it has been adopted in the Houses of Parliament, the United States Senate, several of our northern mines, and many of the prisons and hospitals throughout the country. The graduations for each instrument are obtained by actual experiment by means of machinery made for the purpose, so that the indications of all are as comparable with each other as the weight or measure of ordinary substances.

The indications are shown by means of the large dial and hand, and five smaller ones, as shown in the engraving. The whole circumference of the large dial is divided into 100 parts, and represents the number of feet up to 100 traversed by the current of air. The five smaller dials are each divided into ten parts only, one revolution of each being equal to ten of the preceding dial, and representing 1,000, 10,000, 100,000, 1,000,000, and 10,000,000 respectively. By means of the large dial the low velocity of 50ft. per minute is measured, and by the smaller ones continuous registration is extended up to 10,000,000ft., or 1,893 miles, being practically beyond what the most extended observations can require. Jewelling of the pivots and bearings ensures the utmost delicacy of action. By moving the small catch *a* backward or forward the works are put in or out of gear without affecting the action of the fans; this prevents the injurious effect of stopping them suddenly, and enables the observer to begin or end his observations to a second. A small handle with universal joint accompanies the instrument, and may be screwed in at the base; by putting a stick through this it may be raised or lowered to any required height and used in any position.

The instrument is read off by writing down the position of all the hands. For this purpose the operator places the instrument before him, with the 0 on the outer circle facing him. The first circle on the left-hand indicates hundreds of feet, the next thousands, the third tens of thousands, the fourth hundreds of thousands, and the last circle to the right of the 0 marks millions. He begins to write down the position of the hands with the million circle, and then goes round from right to left, always writing down the lowest of the two numbers if the hand is between two. Let us say that the hand on the millions dial is at 0, the hundred-thousands between 2 and 3, the ten-thousands between 7 and 8, the thousands between 1 and 2, the hundreds at 5, and the large hand which marks units and tens at 73. The millions hand would be omitted, as it has not reached 1, and the remaining numbers would run 271,573. The instrument is then put in the current to be measured, and when removed after a given time is read in the same way; the first being deducted from the second reading gives the velocity (uncorrected) in feet during the time. A simple table is provided by means of which (in strict observations) allowance may be made for the difference caused by inertia at high and low velocities. This excellent little instrument promises to be of the greatest utility in investigations connected with ventilation and draughts. It is manufactured by Mr. L. Casella, the philosophical instrument maker, of Hatton Garden.

THE MANCHESTER STEAM USERS' ASSOCIATION.

THE last ordinary monthly meeting of the executive committee of this Association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, October 26, Mr. Hugh Mason, Vice-President, Ashton-under-Lyne, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 167 visits of inspection have been made, and 404 boilers examined, 274 externally, 7 internally, 6 in the flues, and 117 entirely, while in addition 4 new boilers have been tested by hydraulic pressure, and specially examined both as regards their construction and equipment of fittings. In the boilers examined 61 defects have been discovered, 3 of them being dangerous. Furnaces out of shape, 3; fractures, 6; blistered plates, 8; internal corrosion, 14—2 dangerous; external ditto, 6—1 dangerous; internal grooving, 4; safety valves out of order, 1; pressure gauges ditto, 1; boilers without glass water gauges, 6; without pressure gauges, 4; without feed back pressure valves, 8.

Five explosions have occurred during the past

month, by which nine persons have been killed, and twelve others injured. These explosions occurred with such rapidity at the close of the month that it was with difficulty they could be kept pace with and full particulars obtained. In four cases, however, the scene of the catastrophe has been visited by officers of the Association. Not one of the explosions which have taken place during the past month, or any referred to in this report, have occurred to boilers under the charge of the Association. The following is a statement of explosions from September 25 to October 22, 1869, inclusive:—September 26, plain cylindrical, egg-ended, externally-fired, 1 killed, 1 injured; October 6, double-flued furnace, internally-fired, 2 killed, 6 injured; October 14, plain cylindrical, egg-ended, externally-fired, 2 killed, 1 injured; October 18, plain cylindrical, egg-ended, externally-fired, 2 killed, 1 injured; October 19, single-flued or Cornish, internally-fired, 2 killed, 3 injured. Total, 9 killed, 12 injured. At the meeting at which the report from which the foregoing is extracted was read, the following resolution was passed:—"That a special edition of the chief engineer's report for the present month be sent to every coroner in the United Kingdom, with a circular letter signed by the President, calling attention to the verdicts given at the inquests therein referred to, and also that the same be accompanied by a copy of the report presented at the recent meeting of the British Association in Exeter by the committee appointed to consider 'How far coroners' inquisitions are satisfactory tribunals for the investigation of boiler explosions, and how these tribunals may be improved.'"

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE ordinary monthly meeting of members was held at the City Terminus Hotel on Saturday, the 6th inst. Mr. Newton, of the Mint, occupied the chair. After the transaction of the ordinary business, Mr. John Humes proceeded to read a paper on the "Warsop Aero-Steam Engine." After describing the earlier experiments made by Mr. Warsop in his attempts to reduce to practice a theory which had long occupied his mind, the author went on to explain the construction and arrangement of the most recently made engine on the Warsop principle. This was a marvellously simple piece of mechanism, and comprised merely the addition of an air-pump and conducting pipes to an ordinary high-pressure steam engine. The boiler in this case was on the Cornish multitubular plan. The radiating surfaces of the pipes were clothed, and the feed water was heated by the exhaust steam to 200deg. The air on its first emission from the pump was conducted into the vessel wherein the engine discharged its exhaust steam. It then passed down the chimney through a coiled pipe which led to the bottom flue of the boiler, the latter being set on the split draught principle. Thence it passed on to the smoke box or combustion chamber, and through a coil of sufficient size to allow of cleaning. The heated air was then conducted through the under flue to the front of the boiler, into which it was admitted by a check valve. A perforated pipe laid along the bottom of the boiler received the air and distributed it evenly. The lengths of pipe were as follows:—Feed heater, 12ft.; exhaust pipe, 13ft. 6in.; coils, 58ft.; in all 83ft. 6in., the total surface being 36 square feet. The boiler had a total heating surface of 130 square feet. A trial of this engine yielded most favourable results. In fact, the gain demonstrated by its use was equal to 47 per cent. as compared with the duty performed by the same engine with steam alone. They had thus, therefore, produced a machine which, when worked as an ordinary steam engine, performed its brake duty as well as any average commercial engine not designed to work with a high rate of expansion, whilst the addition of the pneumatic arrangement enhanced very considerably the amount of its useful duty. By the contact and intermingling of the two elements, a twofold advantage was gained. The air rose by force of its own levity through the water, which thus became "aërified" and subdivided, and the air itself on rising above the surface of the water, became saturated with steam, which assisted lubrication subsequently when the compound entered the cylinder.

Such is the pith of the invention which Mr. Humes described to the Associated Foremen on Saturday, and which he then explained very elaborately by aid of models and diagrams. It was understood that Mr. Eaton had purchased the patent right of the contrivance, and that several engines on the Warsop principle were now in course of construction by Messrs. Easton and Amos, Messrs. Roby and Co., and other well known engineering firms. A discussion followed the paper, and in this Messrs. Ives, Edmonds, Sisson, Eaton, Irvine, and the chairman joined. In putting the customary vote of thanks to the meeting, the chairman complimented the author of the paper and remarked that, although two historical events—the opening of the new Blackfriars Bridge and the Holborn Viaduct—had that day taken place, and might be supposed to dwarf all other proceedings in the City, yet the sitting of that night would be memorable in the annals of engineering. It might be that the names of Eaton and Warsop would one day become as celebrated as those of Boulton and Watt, and then the Association would regard with satisfaction the fact that the new engine of those gentlemen had been critically analysed and approved of in that hall.

Messrs. Humes and Eaton having acknowledged the conjoint vote of thanks unanimously accorded to them, the sitting was formally closed.

UTILISING THE WASTE STEAM OF LOCOMOTIVE ENGINES.

THE invention we are about to describe relates to the utilisation of the waste high-pressure steam and heat of locomotive engines. It has been patented by Mr. A. Dillon, of Dublin, who proposes thus to increase the heating power of the furnaces and to effect an important saving in fuel, and at the same time to utilise the waste heat of the engine. By the term "waste steam," is meant the steam which is given off from the cylinders through the blast pipe after its initial work is done, or the waste steam from the safety valves, and by "waste heat" is to be understood the heat which is carried off by the steam blast after heating the boiler, and also that heat which ordinarily acts injuriously on the fire-bars and other parts of the furnace, and which is of such little value in the generation of steam. The results of Mr. Dillon's arrangements are that the oxygen contained in one portion of the waste steam and the atmospheric air which is induced or impelled by another part of such steam is caused to come in contact with, and either prevents the formation or promotes the combustion of, the carbonic oxide, which is so frequently and so detrimentally evolved from the burning fuel, thus greatly increasing the heating powers of the furnace. At the same time the steam which is brought to bear upon the furnace bars has the effect of cooling them, thus preventing the adherence of clinkers.

The apparatus for effecting these purposes is as follows:—A bell-mouthed steam pipe leads from the side of the blast pipe to the fire-box, where it is formed into a zig-zag coil beneath the fire-bars, and terminates in the fire-box or water tank. The pipe of which the coil under the fire-bars is formed is perforated with small holes through which a portion of the waste steam rushes. The steam jets thus produced are caused by the arrangement of the coil to play partially on the fire-bars and partially into the fire, the effect of which is, first, to abstract from and utilise the excessive heat of the fire-bars and keep them cool, thus preventing the accumulation and adherence of clinkers thereon. Secondly, the steam is thus forced into contact with the heated bars, the incandescent part of the fuel, and the carbonic oxide, and is decomposed into its elements, and free hydrogen is liberated. In order to supply a sufficient quantity of oxygen for the combustion of the hydrogen thus liberated, atmospheric air is brought into contact and mingled with it either by the steam which issues from the rear end of the coil of pipe, or from any other part of the coil itself.

THE INSTITUTION OF CIVIL ENGINEERS.

SUBJECTS FOR PREMIUMS.

THE Council of the Institution of Civil Engineers invite communications on the subjects comprised in the following list, as well as upon others; such as, first, authentic details of the progress of any work in civil engineering, as far as absolutely executed (Smeaton's account of the Eddystone Lighthouse may be taken as an example); second, descriptions of engines and machines of various kinds; or, third, practical essays on subjects connected with engineering, as, for instance, metallurgy. For approved original communications, the Council will be prepared to award the premiums arising out of special funds devoted for the purpose.

1. On steam and hydraulic cranes, and on the application of steam power in the execution of public works.
2. On the different systems and the results of the use of road traction engines.
3. On the theory and details of construction of metal and timber arches.
4. On land-slips, with the best means of prevent ing or arresting them, with examples.
5. On the principles to be observed in laying-out lines of railway through mountainous countries, with examples of their application in the Alps, the Pyrenees, the Indian Ghats, the Rocky Mountains of America, and similar cases.
6. On the working expenses of railways.
7. On railway ferries, or the transmission of railway trains entire across rivers, estuaries, &c.
8. On the systems of fixed signals at present in use on railways.
9. Description of a modern locomotive engine, designed with a view to cheapness of construction, durability, and facility of repair.
10. On the cost of maintenance of railway locomotives.
11. Description of continuous brakes which have been extensively employed on railways, and the general results.
12. On the most suitable materials for, and the best mode of formation of, the surfaces of the streets of large towns.
13. On the construction of catch-water reservoirs in mountain districts, for the supply of towns, for irrigation, or for manufacturing purposes.
14. Accounts of existing waterworks; including the sources of supply, a description of the different modes of collecting and filtering water, the distribution to the consumer, and the general practical results.
15. On pumping machinery for raising water, both for high and low lifts.
16. On the principles applicable to the drainage of towns, and the disposal of the sewage.
17. On the employment of steam power in agriculture.
18. On the ventilation and warming of public buildings.
19. On the design and construction of gas works, with a view to the manufacture of gas of high illuminating power; and on the most economical system of distribution of gas, and the best modes of illumination in streets and buildings.
20. Description of successfully applied gas engines.
21. Critical observations on tides, and particularly as affecting coasts, estuaries, rivers, docks, and navigation.
22. On the maintenance, by sluicing, of the Harbours on the Coasts of France, Belgium, and Holland.
23. Description of the sea works at the mouth of the River Maas, and the effects produced thereby.
24. On the construction of tidal or other dams in a constant or variable depth of water; and on the use of wrought iron in their construction.
25. On the arrangement and construction of floating landing stages for passenger and other traffic, with existing examples.
26. On the different systems of swing, lifting, and other opening bridges, with existing examples.
27. On the measure of resistance to bodies passing through fluids at different velocities, and of fluids passing through pipes and in channels.
28. On the results of the best modern practice in ocean steam navigation, having regard particularly to economy of working expenses, by superheating, surface condensing, great expansion, high pressure, &c.; and on the "life" and cost of maintenance of merchant steam ships.
29. On the practical employment of heated air as a motive power.
30. On ships of war, with regard to their armour, ordnance, mode of propulsion, and machinery.
31. On the measures to be adopted for protecting iron and iron ships from corrosion.
32. On coal mining in deep workings.
33. On colliery explosions, and on the influence of different modes of "getting" coal on the safety of mines.
34. On the present systems of smelting iron ores; of the conversion of cast iron into the malleable state and into steel, and of the manufacture of iron and steel generally, comprising the distribution and arrangement of iron and steel works.
35. On machinery for rolling heavy rails, shafts, and bars of large sectional area, and for forging heavy masses of metal.
36. On steel, and its present position as regards production and application.
37. On the safe working strength of cast and malleable iron and steel, including the results of experiments on the elastic limit of long bars of iron,

and on the rate of decay by rusting, &c., and under sudden and prolonged strains.

88. On machinery for washing lead ores.

89. On the present state of submarine telegraphy, and on the transmission of electrical signals through submarine cables.

The Council will be glad to receive, for the purpose of forming an "appendix" to the minutes of proceedings, the details and results of any experiments or observations on subjects connected with engineering science or practice.

The Council will not consider themselves bound to award any premium should the communication not be of adequate merit, but they will award more than one premium should there be several communications on the same subject deserving this mark of distinction. It is to be understood that, in awarding the premiums, no distinction will be made whether the communication has been received from a member or an associate of the Institution, or from any other person, whether a native or a foreigner.

The communications must be forwarded, on or before February 1, 1870, to the house of the Institution, No. 25, Great George-street, Westminster, S.W., where copies of this paper, and any further information, may be obtained.

TRIASSIC DINOSAURIA.

PROFESSOR HUXLEY has communicated to the new scientific journal "Nature," a note of the utmost importance referring to a very remarkable discovery he has recently made. The note reads as follows:—It will probably interest geologists and palæontologists to know that a recent examination of the numerous remains of Thecodontosauria in the Bristol Museum, enables me to demonstrate that these Triassic reptiles belong to the order Dinosauria, and are closely allied to Megalosaurus. The vertebræ, humerus, and ilium, found in the Warwickshire Trias, which have been ascribed to Labyinthodon, also belong to Dinosauria. The two skeletons obtained in the German Trias near Stuttgart, and described by Professor Plieninger, some years ago, are also unquestionable Dinosauria; and, as Von Meyer is of opinion, probably belong to the genus Teratosaurus, from the same beds. Von Meyer's Platœosaurus, from the German Trias, is, plainly, as he has indicated it to be, Dinosaurian.

As Professor Cope has suggested, it is very probable that Bathygnathus, from the Triassic beds of Prince Edward's Island, is a Dinosaurian; and I have no hesitation in expressing the belief, that the Deuterosaurus, from the Ural, which occur in beds which are called Permian, but which appear to be Triassic, is also a Dinosaurian. It is also very probable that Rhopalodon, which occurs in these rocks, belongs to the same order. If so, the close resemblance of the South African Galesaurus to Rhopalodon, would lead me to expect the former to prove a Dinosaur. I have found an indubitable fragment of a Dinosaurian among some fossils, not long ago sent to me, from the reptiliferous beds of Central India, by Dr. Oldham, the Director of the Indian Geological Survey. Further, the determination of the Thecodonts as Dinosauria leaves hardly any doubt that the little Ankistrodon from these Indian rocks, long since described by me, belongs to the same group.

But another discovery in the same batch of fossils from India leaves no question on my mind that the Fauna of the beds which yield Labyrinthodonts and Dicynodonts in that country represents the terrestrial Fauna of the Trias of Europe. I find, in fact, numerous fragments of a crocodilian reptile, so closely allied to the Belodon of the German Trias that the determination of the points of difference requires close attention, associated with a Hyperodapedon, larger than those discovered in the Elgin Sandstones, but otherwise very similar to it. Thus, during the Triassic epoch, extensive dry land seems to have existed in North America, Western and Central Europe, Eastern Europe, Central India and South Africa, as it does now; and throughout this vast area, the Dinosauria—the links between reptiles and birds—seem to have been represented by not fewer, probably by many more, than nine or ten distinct genera. I hope, shortly, to have the honour of placing the details of the researches into the structure and distribution of the Dinosauria in which I have been engaged for the last two years, and of which the above notice is one of the results, before the Geological Society.

EVERITT'S ACOUSTIC TELEGRAPH.

A SERIES of experiments with the newly-invented Acoustic Telegraph were recently made at the Fulton Ferry Houses, Brooklyn, in the presence of a number of gentlemen, who were as much astonished as gratified at the accuracy of the general messages that were transmitted by the acoustic telegraph through wires connecting two houses 150 yards from each other. The first message sent was that of Rev. Dr. Deems, "He that hath ears to hear, let him hear." The Rev. Dr. Hall asked, "How long before the new bridge is to be built, and what about stocks in it?" Mr. Samuel Orchard inquired, "Can a man be held responsible for the place of his birth without having been consulted by his parents?" The reporter of the New York "Tribune," from which paper we take these particulars, asked, "What is the time at the ferry?" and Dr. Boscowitz inquired "the relative diagnosis between rubeola and scarlatina." These messages were all transmitted safely, and much more accurately rendered than ever could have been anticipated.

The invention is a battery that works without electricity through a wire that does not call for the protection of insulators, nor tall, massive poles, and that delivers a message through wire, of any length, one-eighth of an inch in diameter, submerged in water, buried in the ground, or suspended in the air. The battery consists of a solid iron cylinder one foot long or more, and four inches in diameter in facial and general, but toward the other end, which becomes conical and tapers like a Minie ball, is an aperture, admitting the entrance of a metallic wire, the medium of communication, the whole supported by solid iron frame work, and weighing not more than 100 pounds. At the facial end of the cylinder is a hollow hemisphere of iron, whose interior surface is covered with silver plate, constituting an elliptical mirror having a solid rim one inch in diameter. The face of this rim is ground so smooth that when it is placed in contact with the cylinder no air can intervene, and it is held and kept in this position by a strong spring twelve inches long, arched above, and supported by the frame-work, and curved below, so as to form the signal key, by which the battery is worked and made to evolve sounds from the organic atoms of the air which surround and press upon the fan of the rim and of the cylinder, with a force equal to 15lb. on the square inch, the moment one face is separated from the other. The distance of this separation is graduated by two metallic bars, which constitute the Diatomic Staff, and from each bar a different order of sound is created, called the vowel and the consonant sounds respectively. By uniting in regular order the first and second orders of sounds, the Fulcimen or third order is produced. By uniting the second and first order, the Bifulcimen or fourth order is generated, and in commingling together the first and second primary orders, the Valorem or fifth order of sound is created, and together they represent and express, under specific symbolic formula of sounds, each letter of the English Alphabet, and each Arabic Notation; and each one is so characteristic and expressive of itself that no mistake can occur in translating a message.

The inventor is Dr. Lancelot Hope Everitt, of New Orleans, La., who was elected a member of the Royal College of Surgeons in Edinburgh some years ago. The doctor's theory is that sound is a triune molecule of matter, silent inertia, impulsive force, and explosive sound, and exists in all the organic atoms of the world. That he can evolve these molecules from the organic atoms of the air in such a way by means of his acoustic battery as to collect them into two dissimilar units of sound, which he converts into two primary orders. When thus evolved the hemispheric mirror reflects them through the solid cylinder, which then inducts them into the cone of the wire, through which it passes with great velocity to the distant end of the wire. This end is all the time in contact with a glass bell made for the purpose. When a message is about being sent a tattoo is sounded by the battery, and this rings the bell so loud that you can hear it twenty feet off. The message then follows in symbolic order, and as they chime their intonations upon the bell they are easily interpreted by the receiver of the message.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular November 11.)

IN most branches of the chemical trade there has been increasing activity throughout the week past, and it is anticipated that, at the turn of the year, a considerable advance will be established in the values of the staple articles. In minerals the business effected has been rather under the average; prices, however, remain very firm. There is little doing in metals, with the exception of iron, in which large transactions have taken place; but, as an endeavour is made to establish an advance of 20s. in manufactured iron, a falling off in orders is certain to result. Soda: for soda ash, prices still rule at £7 to £7 5s. for 48. Caustic meets with a steadier sale at £13 7s. 6d. to £13 12s. 6d for 60. Crystals rather easier, at £3 17s. 6d. to £4. Bi-carbonate dull, at £9 10s. Nitrate of soda: still receding from the late forced rise, sells now at 15s. 6d. to 16s. per cwt. Potash: muriates offering in small quantities at £7 to £7 5s. for 80, for later spring delivery. Saltpetre: inactive, and at last week's quotations. Alum: in continued home and foreign request, at £6 5s. per ton, for loose lump, £7 in export barrels, and £7 for ground. Ammonia: sulphate still scarce, and selling at £15 5s. for secondary, to £17 7s. 6d. for fine white. Copperas: green and rusty values remain stationary. In dry a largely increased business has taken place at £2 10s. Chloride of iron, 52s. Pyrites: unaltered in value, with a steady consumption. Calcined wanted, at 44s. 6d. to 44s. R.C. Lime: in phosphate not much has been done, and prices remain at 52s. 6d. for 65. Bleaching powder readily obtains £8 5s. to £8 10s. for 35, at which large sales have been effected. Disinfectants meet with an active sale, especially among farmers dreading the cattle disease, price as before, 5s. 3d. per cwt. Manganese: is rather dull, with no change in prices. Acids: a considerable business in tartaric, at 1s. 1½d. for foreign; English ground, 1s. 2¼d.; citric, 2s. 5d; oxalic, 7¼d.

METALS.—Iron: Scotch pigs have advanced to 54s. 11d. to 55s. 2d., at which they closed firm. Cleveland very firm, at 44s. 6d. for forge, to 49s. 6d. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 45. Copper: no alteration in this. English tough, £72 to £73; Chili Slab, £68. Tin: is weaker. English, £122 to £123; Straits, £124. Lead: in good demand, and present prices are readily obtainable. P.G. best English soft pig lead, £18 15s. Spelter: some large sales have been made. English nominally quoted at £20 10s.; Silesian, special brands, £19 15s. to £20; Hard spelter, for export, £16 5s. to £16 10s.

Obituary.

IT is with sincere regret that we record the death of the great modern philanthropist, George Peabody, whose name will remain dear to both Englishmen and Americans. He died on the 4th inst., in Eaton-square, whither he had but lately arrived from the United States. Mr. Peabody had been in failing health for some time past, and was on his way southward, in the hope that a milder clime might restore him, when death overtook him, in the 74th year of his age. The deceased gentleman devoted a large portion of his fortune to promoting the interests of science and education, as well as to ameliorating the condition of the poorer classes. He gave immense benefactions to Harvard University, to the Southern Educational Fund, and to charities in his native State of Massachusetts, the exact amount of which was probably known to no one but himself. At the time of the Great Exhibition of 1851, Mr. Peabody redeemed the good name of his countrymen by promptly supplying a sum of 15,000 dollars, which was required in order to place the contributions of America in orderly array, and to save that country from putting in an appearance quite unworthy of its public and private enterprise. In our country—that of Mr. Peabody's adoption—he bestowed on the poor of London upwards of a quarter of a million of money, to be laid out for their benefit. Such an act of princely munificence is without a parallel, and stands out the more prominent from the fact that the donor declined all the numerous offers of honours which were made to him, contenting himself with the reflection that he would be best remembered on both sides of the Atlantic as plain George Peabody.

Legal Intelligence.

VICE-CHANCELLORS' COURT.

NOVEMBER 10.

(Before Vice-Chancellor SIR R. MALINS.)

POUPARD *v.* FARDELL.

THIS bill sought to restrain the making of "skids" (for skidding wheels) with shoes according to the pattern of those the subject of a patent taken out by the plaintiff in January, 1859, for delivering up of all skids in the defendant's possession, and for an account. The plaintiff was a scale and machine maker, and the defendant was a carman in the neighbourhood of the docks, and the discovery of the alleged use by him of plaintiff's skids in February, 1868, was the cause of the present suit. The case was opened on Monday, continued on Tuesday, and occupied the whole day, the further hearing being appointed for Thursday. The plaintiff's various workmen, and Colonel Philpot, and two soldiers of the Royal Horse Artillery were examined in court *viva voce*.

Mr. Glasse, Q.C., and Mr. Bovill appeared for the plaintiff; Mr. W. W. Mackeson, Mr. Stevens, and W. W. Cooper appeared for the defendant.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

MESSRS. DAWSON and CHRISTY (Lille).—We have replied to your communication by post.

RECEIVED.—C. M.—J. F.—J. G.—T. and F.—E. B.—R. J. W.—C. W. M.—H. S.—T. and P.—F. H. W.—G. B.—G. W. H.—S. E.—F. H.—J. L. and Co.—J. H.—E. S.—P. D.—G. F.—S. K.—J. L. N.—S. and J.—H. O.—C. G.—J. W.—E. Meetings for the Week.

MON.—Society of Engineers.—On "The Need for further Experiments on Strength of Materials," by Mr. Charles J. Light, at 7.30 p.m.

TUES.—Institution of Civil Engineers.—Discussion upon M. Gaudard's paper on "The Strength and Resistance of Materials," and, time permitting, a paper will be read on "Public Works in the Province of Canterbury, New Zealand," by Mr. Edward Dobson, A.I.C.E., at 8 p.m.

Naval, Military, and Gunnery Items.

HIS Majesty the King of Portugal has awarded a silver medal and a diploma to Captain John Hesketh, master of the British vessel "British Queen," of Barrow, Lancashire, for having on the 19th June, 1869, saved two of the crew of the Portuguese fishing smack "Born Jesus," off Cape St. Vincent.

THE Duke of Cambridge has issued an order to the effect that soldiers who have been so fortunate as to save life shall be permitted to wear the decorations they have so acquired on the right breast. The navy will be disappointed if Mr. Childers does not follow the example which the Field-Marshal Commanding-in-Chief has set him.

A STEAM travelling crane, supplied by Messrs. Taylor and Co., of Birkenhead, for use alongside No. 2 dock in Chatham Dockyard, to be used in the construction of the "Sultan" armour-clad ship, has just stood a successful test. It was tried up to 17 tons, while it is required to lift only 15 tons; and acted very satisfactorily.

THE issue of the medals for the campaign in Abyssinia has been considerably delayed by the death of the late Master of the Mint, and by the necessity of having the name of each individual officer or soldier engraved on the medal to be given to him. Many of them have, however, now been distributed, and the remainder will soon be delivered.

BETWEEN 6 and 7 on Thursday night week the "Avon," a large steamer trading between Newport and Bristol, came into collision off Pill, a few miles below Bristol, with the steamer "Athlete." The "Avon" sank in five minutes. Twenty passengers were on board, and were all rescued with difficulty in the steamer's own boats. The crew swam ashore. Hundreds of pigs, sheep, and other animals were drowned.

A FINE new self-righting lifeboat, 33ft. long has been purchased with the proceeds—amounting to £500—from penny readings in different parts of the kingdom. The boat is to be stationed at Wells, on the Norfolk coast, under the management of the National Lifeboat Institution. It is to be publicly launched at its station on the 12th inst., when the Countess of Leicester will name the boat. To Mr. E. B. Adams, surgeon, of Bungay, is due the great credit and perseverance of organising and collecting the "Penny Readings" Lifeboat Fund.

THE artillery experiments at Finspong, in Sweden, have been completed, and the new 11½in. gun, which is made entirely of Swedish iron, has met with general approval both among the Swedish and Danish artillerists. It was fired from a distance of 580ft. at a target made of six plates of iron, each 2 in. thick, and backed with strong wooden beams. About 20 yards behind it was a wooden target 2ft. thick, leaning against an embankment of gravel. The conical projectile of the gun, weighing 150lb., pierced both targets and buried itself to a depth of 8ft. in the embankment.

SOME interesting experiments have been carried out at Portsmouth for testing the relative effects of gunpowdee and gun-cotton under equal and unequal conditions, and for ascertaining the comparative action of the regular service fuse used in firing mines, and of the new detonating fuse invented by Abel, the chemist to the War Department. The gun-cotton was in most instances used in the forms of discs and cylinders, and when placed in proper position gave excellent results; but it appears by slight carelessness the greater portion of the advantage is lost.

THE pattern wrought-iron carriage and platform for 12-ton rifle guns, now under course of construction by Colonel Clerk, R.A., at the Royal Carriage Factory, Woolwich, from designs submitted by Captain Moncrieff, of the Edinburgh Militia Artillery, will shortly be completed. With a view to ascertaining its working qualities it is intended to fire a few rounds at Woolwich from a 9-inch 12-ton rifled muzzle-loading gun mounted on it, using 250lb. shot, and battering charges of 43lb. of powder. If the working of the carriage and platform should be found to be satisfactory, it will then be forwarded to the School of Gunnery at Shoeburyness, for use in extensive experiments.

A COMMITTEE has been formed at Sheerness, with Vice-Admiral Warren, commander-in-chief at the Nore, as chairman; Dr. Lisburne, staff surgeon, her Majesty's Reserve, as treasurer; and Mr. H. F. Pullen as secretary; for the purpose of collecting funds for the relief of the widows and orphans of those who were killed by the lamentable explosion on board her Majesty's gunboat "Thistle," on the 3rd inst., by which eight widows and eleven orphans were thrown into mourning. Subscriptions will be thankfully received by the treasurer and the following gentlemen:—Mr. Hugh F. Pullen, R.N., secretary, Sheerness; Mr. J. W. Ashby, C.B., R.N., secretary, Portsmouth; Mr. Richard Munday, R.N., secretary, Devonport; Mr. Henry G. Barlow, R.N., secretary, Queenstown; Messrs. Woodhead and Co., 44, Charing-cross, London; and Messrs. Stilwell and Co., 22, Arundel-street, Strand, London. Bankers, London and County Bank.

Miscellanea.

THE annual dinner of the Society of Engineers will take place at the Westminster Palace Hotel, on Friday, December 17.

LAST week a shock of earthquake, which lasted a few seconds, took place at Sebastopol. Furniture in the houses was shaken, and even upset.

LORD HOUGHTON goes to Egypt as representative of the Royal Geographical Society at the opening of the Suez Canal, by invitation from the Viceroy.

A HEAVY snow storm which recently fell in Italy broke down the telegraphic wires in many places in the interior of Bologna, and caused other damage along the line.

THERE has been a severe earthquake at Manilla. Every building was shaken. Walls were thrown down. Many accidents occurred at Manilla and neighbouring provinces.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending November 6, was 3,838. Total number since the opening of the Museum, free daily (May 12, 1858), 1,678,459.

IT is said that there are only two persons in the United States who have not communicated their views on the Byron question to the newspapers, and they are citizens of Cape Cod, who went off mackerel fishing six weeks ago, and have not returned.

THE number of Cornish pumping-engines reported for September is 20. They have consumed 1,158 tons of coal, and lifted 7·5 million tons of water 10 fathoms high. The average duty of the whole is, therefore, 44,360,000lb., lifted 1ft. high, by the consumption of 112lb. of coal.

THE castor bean, from which the oil is made, is becoming an important industry in Perry country, California. One prominent dealer received at his warehouse 1,000 bushels in one day, paying 3 dollars 18 cents. per bushel. It yields more bushels in the acre than wheat.

THE operations of the diggers at the Sutherland Gold Diggings have during the last week or two been interrupted by unfavourable weather, and the success of those employed has not been equal to that of former mouths, so that it is generally believed gold digging in Sutherland is, for the present at least, at an end.

THE inauguration of the first railway constructed in Wallachia, from Bucharest to Guirgevo, has just taken place, in presence of the representat ves of the foreign Powers. The line, which is not quite 20 miles in length, was commenced in 1863, so that the works have progressed at the rate of 3½ miles per annum.

A HANDSOME free library was opened by the Mayor of Tynemouth at North Shields yesterday week. It is the first that has been started in the Tyneside towns, and is a very complete establishment, consisting of a circulating library of over 13,000 volumes, a large reading-room, reference library, museum, and science and art classes.

THE recent gales have done so much damage to the South Garl Breakwater at the mouth of the Tees that it has been resolved not to proceed further with the constructing of it until some eminent engineer shall have given his opinion as to the desirability of continuing the tipping of the immense quantities of slag from the various iron-works on Teeside.

AN improvement in the manufacture of horse collars has just been devised by a Philadelphia mechanic. The collar, being stuffed with elastic cork, is light in weight, and adapts itself to the shape of the animal as readily as if it was moulded. It is highly elastic, does not chafe or gall the neck, and the cork being a non-conductor, injury from the heat is prevented.

THE coal and coke trade of Northumberland and Durham is growing better, and the prospects are more cheering. The pig iron trade is in a most satisfactory state. From the monthly returns of the Cleveland Ironmasters' Association it appears that the make amounted to 106,685 tons, an increase of nearly 15,000 tons compared with the same time last year. The foreign shipments have been heavy, amounting to 13,716 tons, an increase of about 3,000 tons.

THE Great Central Belgian Railway Company has just laid down some Bessemer steel rails on the Lodelinsart incline near Charleroi; these rails were furnished by the Barrow Hematite Steel Company at £11 18s. 6d. per ton, with delivery in trucks at Antwerp, a guarantee for seven years being also given. Some iron rails of good quality placed three years since upon the incline have recently been found to have been quite worn up in that period.

THE number of visitors to the South Kensington Museum during the week ending November 6, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 12,214; Meyrick and other galleries, 1,420; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,590; Meyrick and other galleries, 90; total, 15,314. Average of corresponding week in former years, 9,375. Total from opening of Museum, 8,931,296.

THE Registrar-General reports that the population of Victoria increased in the second quarter of the year 1869 by 6,623 persons, viz., 3,302 males and 3,321 females, and he estimates the number of the population on the 30th of June, 1869, at 696,161, there being 391,146 males and 305,015 females. During the quarter the gain by excess of births over deaths was 3,988, viz., 1,813 males and 2,175 females. The gain by excess of arrivals over departures was 2,635, viz., 1,489 males and 1,146 females.

WE read in an American paper that a happy thought suggested itself to an engineer in want of tracing paper and unable to procure it readily, to try petroleum. To his surprise he found the experiment extremely satisfactory, and by coating the paper with the petroleum and pressing it between blotters to extract the excess of oil, he obtained a paper in a few minutes which was superior to anything that could be found elsewhere, taking as readily as ordinary paper any marks with writing ink, Indian ink, or colours.

ACCORDING to advices from San Francisco, it appears that a Japanese immigration is likely to be introduced into California simultaneously with that from China. A German named Schnell, who had been for a long time a resident of Japan, came to El Dorado county in June last, and made a purchase of lands for the purpose of establishing a Japanese colony, to be conducted upon the co-operative labour system, to engage in the culture of the tea plant, the oil plant, wax and mulberry trees, and the manufacture of silk, and the results thus far are alleged to have been very successful.

THE "Melbourne Argus" states that attention is being drawn in different parts of Australia to the alterations which the climate is undergoing in consequence of the systematic denudation of tree-covering which the surface of the country is being subjected to. It is shown, for example, that in the case of the Ballarat district the destruction of the timber has been accompanied by a corresponding diminution in the rainfall, and that since 1863 there has been a more or less regular reduction—from 37·27in. in 1863 to 17·23in. in 1868. During the first seven months of the present year, and including two of the ordinarily wettest, the rainfall has been only 11·20in. The government of Victoria have appointed an inspector of State forests, whose duty it will be to prevent the waste of timber and the reckless destruction of live wood, and at the same time to establish nurseries of forest trees in various parts of the colony. The appointment has been conferred upon Mr. Ferguson, late gardener to Mr. Hugh Glass.

In reference to the well-established fact that water, after having been deprived of air as much is possible, either does not boil at all when heated, or does so with violent, sudden starts and concussions, some experiments have been made by Kremers, who observed that, in order to assist in expelling air from water, the addition of spirits of wine, in the proportion of one part of the latter to three of the former, is very useful. He cautions against a danger which exists when such a mixture is heated too rapidly, since it is very apt to boil over, especially after a portion of the spirit has evaporated. It is rather curious, says the "Quarterly Journal of Science," that though both the water and spirits of wine were pure, the mixture when boiling should assume a greenish-yellow hue, which disappears again on cooling. The boiling-point of fluid easily becomes as high as 109 deg. As a result of a large number of experiments, the author finds that water, as fully deprived of air as possible, may be heated as high as from 108 deg. to 200 deg. C., without boiling permanently.

All who have occasion to make use of tracing paper in their professional duties will be glad to know that any paper capable of the transfer of a drawing in ordinary ink, pencil, or water-colours, and even a stout drawing-paper, can be made as transparent as the thin yellowish paper at present used for tracing purposes. The liquid used is benzine. If the paper is damped with pure and fresh distilled benzine, it at once assumes a transparency, and permits of the tracing being made, and of ink or water-colours being used on its surface without any "running." The paper resumes its opacity as the benzine evaporates, and if the drawing is not then completed, the requisite portion of the paper must be again damped with the benzine. The transparent calico on which indestructible tracings can be made was a valuable invention, but this new discovery of the properties of benzine will prove of further service to many branches of the art profession, in allowing the use of stiff paper where formerly only a slight tissue could be used.

The island of Jersey is in a fair way of shortly possessing its first railway—a species of locomotion never yet witnessed by a large portion of the inhabitants. The States recently met especially for the consideration of the bill, and unanimously agreed to it. The line is to run between St. Helier and St. Aubin (formerly the chief town and port of the island, but now completely shorn of its former glory). The line is to round St. Aubin's Bay, near to the main road (a distance of four miles), with intermediate stations. The line is to be formed by a limited company, composed, it is understood, of a small number of English gentlemen, who have in view the contemplated harbour of Noirmont, near to St. Aubin, where it has been for some time past proposed to establish a harbour which will be accessible to the mail packets at all states of the tide. The company is bound to commence the undertaking within three months after the bill has received the sanction of the home Government, and to complete it within twelve months. The line will be a single one.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—1200, 1222, 1228, 1255

Buildings and Building Materials—1227, 1236, 1243 1244

Chemistry and Photography—1178, 1207, 1224, 1242, 1243

Cultivation of the Soil, including agricultural implements and machines—1188, 1239, 1240, 1251

Electrical Apparatus—1250

Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—1202, 1211, 1219, 1230, 1234, 1235, 1237, 1258

Food and Beverages, including the apparatus for preparing food for men and animals—1187, 1195, 1217, 1220

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c.—1183, 1191, 1194, 1196, 1198, 1201, 1204, 1205, 1213, 1215 1223, 1226

General Machinery—1240, 1245, 1249

Lighting, Heating, and Ventilating—1181, 1199, 1215

Metals, including apparatus for their manufacture—1197, 1203, 1206, 1212, 1231, 1256, 1260

Miscellaneous—1177, 1179, 1186, 1189, 1209, 1221, 1238

Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—1182, 1185, 1190, 1192, 1208, 1210, 1216, 1218, 1225, 1229, 1233, 1240, 1246, 1248, 1252, 1254

Ships and Boats, including their fittings—1173, 1214

Steam Engines—1222

Warfare—1180, 1184, 1193, 1232, 1247, 1257, 1259

1173 L. Eggert and O. E. Pohl, Liverpool. *Vessel of war.* Dated April 16, 1869.

The invention consists in the peculiar form of the vessel. The following is a description of midship section:—The displacement being calculated, and the area of the greatest midship section determined, the inventors construct the same, marking the load water line according to the calculation. They make another mark below the water line down to that point where projectiles passing through the water and touching the body of the vessel will prove ineffective. From this mark downwards, the under body must be constructed according to the size of the vessel of wood only, while all above is constructed of iron.—Patent abandoned.

1177 S. Harrison, Liverpool. *Ventilating sewers.* Dated April 16, 1869.

The apparatus consists of a manhole and ventilating cover combined with movable sludge box or mud basket; in the arrangement of a charcoal basket, which is used for purifying the noxious gases arising from the sewer or drain and escaping through the ventilating cover in an overflow or drain pipe connected with the manhole and extending into the sumphole at the bottom of the manhole shaft, where it is trapped in a flushing valve fixed on the edge of the sewer or drain, where it joins the shaft; in a portable winch for raising the said flushing valve; in a flushing box connected with the above, for flushing the sewers and drains and lamphole cover, for the purpose of lighting and ventilating sewers and drains when workmen are engaged therein; and in a trap gulley made with a hopper and movable sludge box, and in a flushing valve or differential outlet pipe for subsidence tanks and cesspools.—Patent completed.

1178 G. T. Bousfield, Brixton. *Hydrocarbon oils.* (A communication.) Dated April 16, 1869.

This consists, first, in treating heavy hydrocarbon oils for the purpose of deodorising them by distilling off a portion containing the odorous matters, and then stopping the distillation, leaving the main body of the oil in the still free from the characteristic odours of heavy hydrocarbon oils, and having when cooled only a slight smell like a sweet fatty oil. Second, in the combination with a still suitable for distilling oils, the superheating coil within the still, with its steam pipe, outlet pipe, and return pipe, and their stopcocks.—Patent completed.

1179 A. F. Craig, Paisley. *Cutting pasteboard.* Dated April 16, 1869.

The cutting is effected by circular knives fixed on spindles, which are made to revolve by any convenient gearing. The sheet first passing longitudinally between one pair of these knife spindles to receive what may be termed the longitudinal cuts; and the strips so formed are then passed without derangement, but in a transverse direction, between a second pair of knive spindles, by which the transverse cuts are produced.—Patent abandoned.

1180 J. H. Johnson, Lincoln's Inn. *Firearms.* (A communication.) Dated April 16, 1869.

This consists, first, in the increased simplicity of the mechanism; second, in the double fastening of the breech by means of a lever cover piece, which admits of the projectile being driven home and centred in the rifled grooves; third, in a peculiar arrangement of the trigger and parts in connection therewith; fourth, in a peculiar safety apparatus for preventing discharges till the breech is properly closed; fifth, in a peculiar system of cartridge extractor; sixth, in a peculiar system of rifled grooves having a sharp twist and narrow projecting ribs between them; seventh, in a peculiar elevation sight, which admits of the correction of lateral deviation arising from any cause, the effects of which are very sensible at long ranges.—Patent completed.

1181 W. E. Newton, Chancery-lane. *Safety gas burners.* (A communication.) Dated April 16, 1869.

A chamber filled with sand or granular mineral matter is applied between the burner and the pipe from which it is supplied.—Patent abandoned.

1182 J. Ives, Thame. *Velocipedes.* Dated April 16, 1869.

The inventor provides a crank transverse frame to carry the seat and foot board, and this frame is suspended on the trunnions of a pair of carrying wheels. Connected with these trunnions are cranked handles, through which rotary motion is communicated to the carrying wheels by the person on the suspended seat. Or the wheels may be keyed to a cranked axle divided in the middle and capable of connection by means of a sliding friction or other clutch.—Patent abandoned.

1183 P. Bogler and H. Kayser, Vienna. *Lifts.* Dated April 17, 1869.

This improved lift consists of four wooden columns, set in a square and united by suitable cross bars. The inner sides of the columns form a slide wherein the lift may rise upwards and downwards as desired. A suitable screw is provided for this purpose, which is turned by a lever or handle below, and passing through a nut fixed to the movable platform or landing.—Patent abandoned.

1184 E. T. Hughes, Chancery-lane. *Firearms.* (A communication.) Dated April 17, 1869.

This consists in the construction of gun barrels with a compound bore, consisting of three sections, one of which at the breech end is a perfectly smooth bore; another section at the muzzle end is a rifled bore (the calibre of this section should be just the depth of the rifling, smaller than the smooth bore section); the third and middle section consists of a tapering bore, which at each end coincides with the bore with which it is connected. The rifling is continued through the middle section to the same depth as the muzzle section, and should be a gaining twist.—Patent completed.

1185 P. Bogler and H. Kayser, Vienna. *Railway tickets delivery regulator.* Dated April 17, 1869.

This consists in causing the button to act by pressure on a lever, the turning point of which is fitted with a spiral spring. The bar actuated by the lever acts on the tickets so that they can pass the slit through which they are delivered. The spiral spring also returns the lever and button to their normal positions when the pressing operation is over.—Patent abandoned.

1186 F. J. Knewstub, James-street, S.W. *Printing.* Dated April 17, 1869.

This consists in printing by the ordinary mode from plates, stones, or otherwise, an ornamental background, outline, or border, in ink or colour, or in gold, silver, bronze, or other metal. A pattern or device is then produced upon the background, outline, or border, with or without ink or colour, or gold, silver, bronze, or other metal, either by stamping, embossing, printing, or other similar means.—Patent abandoned.

1187 H. W. Dee, Sherwood-street, Golden-square. *Bottles and jars.* Dated April 17, 1869.

This consists in making grooves or channels in the neck of the bottle, or in a collar fitting over the neck in such a manner that when the top or cap is forcibly pressed over the mouth, and turned partly round by the hand, the pressure of a spring within the head of the top or cap causes it to move upwards, and to bring pins or studs into grooves or notches made at right angles to the grooves or channels before mentioned.—Patent abandoned.

1188 T. Amies, Peterborough. *Warming greenhouses.* Dated April 17, 1869.

The inventor forms the boiler of the apparatus of a vertical water space, enclosing three sides of a rectangle, the fourth side of the rectangle being merely closed in by a door. At the top of the boiler, the three-sided vertical water space opens into a horizontal water space, which forms the top of the boiler. Below the bottom of the boiler is placed a gas burner, and the products of combustion as they rise up from it are caused to pass in a zigzag direction between water spaces which project out alternately from the opposite sides of the vertical three-sided water spaces, and these horizontal water spaces extend nearly from the one side to the other.—Patent completed.

1189 J. Willats, Stamford-road, N.E., and A. J Martin, Stratford. *Mode of advertising.* Dated April 17 1869.

This consists in the application to ordinary playing cards of announcements in the form of advertisements.—Patent refused.

1190 T. Page, Adelphi, W.C. *Locomotives.* Dated April 17, 1869.

The inventor provides a tank or receiver placed in a horizontal position above the boiler, and secured thereto in any suitable manner. This tank, which is divided into compartments by partitions or otherwise, or traversed by tubes, contains the water to be supplied to the boiler. These tubes open into a smoke box at either end, and the flue tubes of the boiler also communicate with the forward or smoke box proper in the usual manner. The products of combustion after leaving the flue tubes of the boiler are passed through the tubes or divisions of the tank to the area of the smoke box for heating the water contained in the said tank in their passage.—Patent completed.

1191 A. Smith, Mauchline. *Ornamenting hats.* Dated April 19, 1869.

When the colouring matter is applied directly upon the foundation or body, the inventor prepares the same with size, and varnishes the coloured surface when dry to secure it from injury by the weather and render it waterproof.—Patent abandoned.

1192 R. Chapman, Shrewsbury. *Railway fish plates.* Dated April 19, 1869.

The object of the invention is to prevent the screw bolts of railway fish plates and the nuts on them from working loose, and this is accomplished by having a ledge or projection made on the outside of that fish plate against which the nut presses in such a position that when the nut is in its place and pressing against the fish plate, the ledge or projection prevents it from turning round.—Patent abandoned.

1193 J. Horsley, Cheltenham. *Blasting powder.* Dated April 19, 1869.

This consists in the incorporation of nitro-glycerine either with a mixture of powdered aleppo or other foreign gall nuts and chlorate of potash, or with a mixture of powdered galls, cream of tartar, and chlorate of potash, or with a mixture of galls, hard sugar, and chlorate of potash, or with plain mealed gunpowder, so as to form a powerful blasting powder or explosive compound.—Patent completed.

1194 H. A. Bonneville, Sackville-street. *Making hat rims.* (A communication.) Dated April 19, 1869.

The apparatus consists of a cast-iron table resting upon a frame. This table carries the mechanism, which is as follows:—Motion is imparted to the three gearings by a crank; the first gearing is shipped upon the arbor of the crank and actuates the two other gearings. The object of each of these is to impart motion in one direction or the other to the levers by means of the nuts and the screws. The levers oscillate. The screws are wormed some to the right and the others to the left, in such wise that by means of their nuts the levers act simultaneously either in drawing nearer to or in receding from the centre of the apparatus.—Patent completed.

1195 P. Bourchani, Paris. *Raising beer.* Dated April 19, 1869.

A main reservoir is provided with two openings, one for the entrance of the water which is to fill the reservoir, the other for the exit of the water and the emptying of reservoir, the latter opening having a pipe at least 12 yards in length, and plunging for this purpose into a well or drain or other conduit. The first reservoir is in direct communication with a recipient which, fitted near the bar or counter, is intended for the reception of the raised liquids.—Patent abandoned.

1196 W. H. Smith, jun., Salisbury-street, W.C. *Lavatories and taps.* (A communication.) Dated April 19, 1869.

The inventor so mounts and fits the basin that by turning it partially round it is caused to rise or fall, and either close or open the discharge or escape passages instead of employing the ordinary description of plug and shell, tap or cock, for regulating the admission of water.—Patent abandoned.

1197 H. AITKEN, Falkirk. *Treating iron ores.* Dated April 19, 1869.
This consists in coking or carbonising in contradistinction to roasting or calcining the iron ores or ironstones in the open air on a platform or bed of clay, brick, stone, iron, or other material, which may be situated horizontally or at angle to that position (an angle of about one in fifteen is preferred); or in place of using a platform, the iron ores or ironstones may be placed in an open casing on the top of a blast furnace, and when coked or carbonised dropped into the furnace, or they may be treated in an open tower or kiln.—Patent completed.

1198 J. E. WARD, Bredbury. *Hats.* Dated April 19, 1869.
This consists in making hats with a sufficiently stiff but elastic "leather" or lining so secured to the body or shell of the hat that there will be space all round between the "leather" or lining and the body or shell of the hat, equal in depth at least to that of the ordinary "leather" or lining. This "leather" or lining is not attached to the body of the hat at the brim in the ordinary manner, but is secured or suspended from a point or points within the body of the hat, the lower edge being loose and not fast as in the ordinary hat.—Patent completed.

1199 A. V. NEWTON, Chancery-lane. *Friction matches.* (A communication.) Dated April 19, 1869.
The invention comprises, first, a composition containing caoutchouc (or india-rubber) or gutta-percha for the manufacture of matches. Second, the match safe constructed so that the coiled match and tube may be properly secured and used.—Patent completed.

1200 H. Y. D. SCOTT, Ealing. *Pottery ovens.* Dated April 19, 1869.
The novel features in this oven are:—A feeding hopper having a considerable inclination downwards towards the far end of the fireplace, or that which is nearest to the working chamber. Second, inclined firebars to which the fuel descends after it leaves the hopper. Third, a rectangular or horizontal chamber such as is now commonly used in the potteries, and in which the fuel is retained by a reticulated wall or glut, or in some instances such as is used at the copper smelting works, where the depth of the fuel on the firebars is required to be considerable, and the fire is chiefly retained by the masses of slag which collect upon them. It is to this chamber that the fuel introduced into the hopper finally descends.—Patent completed.

1201 S. SHAW, Boston. *Feeding boilers.* (A communication.) Dated April 19, 1869.
In a piston which is fitted to work in a pump, barrel, or cylinder, the inventor forms a chamber which, as the piston moves to and fro in the cylinder, is alternately brought opposite to each one of two apertures, one of which communicates with the source of supply, and the other with the boiler. The centre of the said chamber coincides with the desired water level in the boiler. The chamber is filled with water through the supply aperture, and carries the same to the outlet aperture, through which, if the water in the boiler has fallen below the proper level, this water or a portion of it will flow.—Patent abandoned.

1202 L. GOETZ, Leith, N.B. *Cleansing wool.* Dated April 20, 1869.
This consists essentially in boiling together for about three hours in water the following ingredients in or about the proportions given, namely:—The water, about 250 gallons, is first purified by boiling it with 10lb. to 15lb. of farina for about five minutes. To these 250 gallons of purified water are then added 200lb. of calcined soda or soda ash of a strength of about 90deg. and free from salt, 100lb. of linseed, 72lb. of potash, 72lb. of resin, and 40lb. of caustic soda of a strength of about 90deg. From 40lb. to 45lb. of Olein oil may also be added to increase the washing or cleansing power.—Patent completed.

1203 A. BRADY, Maryland Point, Stratford. *Manufacture of iron.* (A communication.) Dated April 20, 1869.
This consists in mixing and manipulating crude iron ore, ground or reduced to a powder with sulphate of lime, sulphate of soda, sulphate of alumina, or with any alkaline sulphate pulverised, and both articles having been roasted or otherwise assimilated to about equal degrees of temperature. A fusion or smelting of the materials is then to be effected by the usual methods in an ordinary furnace.—Patent abandoned.

1204 F. W. FOLLOWS and J. BATE, Manchester. *Sweeping carpets.* Dated April 20, 1869.
This consists in an improved mode of giving motion to the rotary circular brush forming part of the sweeping apparatus, which is supported on one or two travelling wheels, and on one or two rollers. The travelling wheels are made with an internal toothed wheel gearing into pinions on the end of the rotary brush, or, in some cases, it may be sufficient to make the internal gear in only one of the supporting wheels. Instead of toothed gear as above described, friction surfaces may be used.—Patent abandoned.

1205 N. WILSON, High Holborn. *Sewing machine.* Dated April 20, 1869.
This consists, first, in an arrangement of the mode of obtaining motion for driving the shuttle and feed movement in lock stitch sewing machines. Second, in an arrangement of the several parts for driving and giving motion to the reciprocating radial arm for passing a shuttle from right to left and left to right in lock stitch sewing machines. Third, in the arrangement of a single or chain stitch sewing machine in combination with the improved internal driving wheel and pinion of the same invention for obtaining a more rapid motion to the needle in the same space. Fourth, the arrangement and combination of a silent feed movement as adapted to that class of sewing machines wherein the silent compound feed is driven by a bridle and cam movement in combination.—Patent completed.

1206 F. BARTLE, Pool. *Washing tin ores.* Dated April 20, 1869.
This consists in constructing the "kieves," or vessels in which the washing is effected, of cast iron or other metal, and in forming upon the sides thereof one or more pockets or brackets, in which are placed pieces of wood or other suitable material for receiving the blows of the hammer for producing vibrations.—Patent abandoned.

1207 R. J. ELLIS and C. L. W. FITZ-GERALD, of Laxey, Isle of Man. *Drying chemical and vegetable matters.* Dated April 20, 1869.
The inventors employ a metallic vessel having, at the top, a cover which can be made airtight, and near the top a pipe or nozzle communicating with an exhaust pump; and this vessel they enclose in another metallic vessel, which can be supplied with steam. They place the matters or material to be dried in the inner vessel, then close the door and make it airtight. They now set on the steam, and, as the heat causes vapour to rise from the matters or materials, it is taken off by the exhaust pump, and, in this manner, the matters are thoroughly dried.—Patent abandoned.

1208 R. C. RAPIER, Victoria-street, S.W. *Railway signals.* Dated April 20, 1869.
A signal post is constructed as follows:—First, the inventor makes a base plate, either of iron or timber, of a size proportionate to the intended height of the signal post, and, on this base plate, he makes three or more bosses at equal distances apart, and disposed in the form of an equilateral triangle, a square iron tube or rod, preferably about 2ft. to 4ft. long, and, on to the top of this tube, he screws a diaphragm plate having the same number of bosses as there are on the base plate. Through the next hole of the diaphragm plate the inventor then passes another tube about twice as long as the first tube, and he screws or fixes the lower end of this into the corresponding boss on the base plate. He then tightens it in the boss of the diaphragm plate with a key or wedge. Next, he screws on to the top of the last-named tube another diaphragm plate, and then through the next hole of this diaphragm plate he passes another tube, about three times as long as the first tube, also passing it through No. 1 diaphragm, and fixes it into the corresponding boss on the base plate at the bottom, and so on with any number of tubes or solid bars, the fourth tube in the centre (if so many be employed) being four times as long as the first, and the fifth five times as long and so on.—Patent completed.

1209 W. E. GEDGE, Wellington-street, W.C. *Water meter.* (A communication.) Dated April 20, 1869.
This apparatus is made of bronze, copper, or any other non-magnetic metal or alloy, that is to say, having no influence on the magnetised needle. It is composed of an annular basin, which may be perfectly closed by means of a lid, also annular. The basin and its lid both carry lugs which come opposite each other and are tightened together by bolts. The lid is provided with two tubes or union pipes.—Patent completed.

1210 K. S. MACKENZIE, Gairloch, N.B. *Fences, railings, &c.* Dated April 20, 1869.
The top bar is made of T-iron rolled in any convenient section, but with the peculiarity that the vertical web, projecting downwards from the middle of the other web, is made thicker at its bottom edge than nearer to the other web. Counterpart notches are formed in the tops of the fence standards, and, when those standards are in position, the top bar is applied by threading its vertical web through the notches, and the parts become locked together as by a dovetail joint, whilst the horizontal web of the T-iron bar caps the fence in a neat finished manner.—Patent completed.

1211 H. LEE, Manchester. *Looms.* Dated April 20, 1869.
The inventor uses two warps and four healds. The top warp beam is weighted in the usual way, but the under or back warp beam is weighted in such a manner that, upon the raising of the taking-up catches, it draws the under warp back a certain distance. The healds are worked by means of a well-known machine called the "dobby" or "index machine"; one of the loops of this machine is connected by a cord to a lever, the other end of which, whenever a corresponding perforation occurs in the card which acts on the needle, raises the catches off the taking-up ratchet wheel, and holds them off the wheel for two picks of the shuttle. In gear with one of the carrier wheels of the taking-up motion is a spur wheel mounted on a stud, and having attached to its boss a weighted lever.—Patent completed.

1212 G. GREEN, Aberystwith. *Separating ores.* Dated April 20, 1869.
The inventor uses classifiers in combination with buddles. The classifiers are of graduated sizes, the first in order being the smallest, and the current of water with pulverised ores in suspension flows through them at different speeds, so that, in the first and smallest, the current being the strongest, the largest particles are deposited, and smaller ones in the next, and so on. The matters deposited in each classifier pass off with some water by an outlet at the bottom, and flow thence to buddles.—Patent completed.

1213 W. R. LAKE, Southampton-buildings. *New toy.* (A communication.) Dated April 20, 1869.
The invention consists chiefly in fixing to the interior of any suitable hoop a number of bells of any desired size. These bells may be connected to the hoop by wire or other means of attachment, by preference such as will permit the child using the hoop to remove or replace the bells according to the effect desired to be produced in the hoop.—Patent abandoned.

1214 M. ANDREW, Melbourne, Australia. *Vessels for oil, &c.* Dated April 20, 1869.
A hole is cut in any suitable part of the vessel in the ordinary manner, through which hole the vessel is filled with oil or other liquid. A cap or cover is soldered over this hole, and a central hole is pierced in the cap. In this hole is inserted a tube or pipe slightly smaller in external diameter than the hole, but of sufficient diameter to serve as a tap. The inner end of this tube or pipe is pressed somewhat open for the purpose of preventing its being withdrawn more than a certain distance. Near this end of the tube, a hole is made in the side thereof for the passage of the liquid to be drawn from the vessel. The tube is fitted within a box, tube, or socket which has a cork, leather, or other lining, extending for a short distance from the open end thereof, and made to fit tightly around the tube. In the side of this box tube is a hole which also extends through the cork or other lining thereof, and which corresponds with the hole in the side of the small tube so as to permit the free passage of the contained liquid when the small tube is properly drawn forward.—Patent completed.

1215 W. R. LAKE, Southampton-buildings. *Lamps.* (A communication.) Dated April 20, 1869.
These lamps are constructed with an annular reservoir which surrounds an annular air chamber, and through the centre of the air chamber extends the burning chamber. The latter is connected to the annular reservoir at the bottom by supply pipes, which pass through the air chamber, and at the top by vent tubes, which also pass through the said chamber. At the top of the burning chamber is the burner, which is perforated, the perforated portion thereof being surrounded by a collar, which forms a continuation of the air chamber.—Patent completed.

1216 W. F. REYNOLDS, Commercial-road East, and J. A. MAYS, West-street, Finsbury-circus. *Velocipedes.* Dated April 21, 1869.
The inventors make the framings and supports and the springs of velocipedes so that, as a whole, they may be bent or curved horizontally when they are desired to run out of a straight course.—Patent completed.

1217 W. HOLLOWAY, Lower Clapton. *Making beverages.* Dated April 21, 1869.
On the bottom of a vessel the inventor fixes a spindle which extends nearly to its top. Fitted to the spindle, and free to move thereon, is a tube which also extends nearly to the top of the vessel. On the lower part of the tube, two, three, or more blades are fixed. These are slightly curved and perforated. The bottom edges are flanged, and fit close to the bottom of the vessel.—Patent abandoned.

1218 J. FLETCHER, J. FLETCHER, jun., and W. FLETCHER. *Lubricating wheels.* Dated April 21, 1869.
The inventors apply one or two oil cups which are screwed into the bearings at one or both ends of the axle, and they make a horizontal and one or more radial passages through the axle communicating with the oil cups. The oil is thus conveyed from the oil cup or cups into and through the interior of the axle, and from the interior conveyed by the radial holes or passages into the nave, which is thereby kept constantly lubricated so long as any oil remains in the oil cups.—Patent abandoned.

1219 P. R. HODGE, Adam-street, Adelphi. *Manufacture of cloth.* Dated April 21, 1869.
The inventor takes cotton or linen cloths, known under the name of twilled canvas, or twilled or plain calicoes, and submits it to a chemical process to partially convert the coating of the fibre from which the cotton cloth is made into collodion. This he terms collodionising the cloth. When the cloth is so treated the acid it may have absorbed is neutralised and then washed off perfectly clean. The inventor then takes a pulp made of gelatine and fibre, or it may be made by softening by the heat of steam the parings of skins or hides, and beats them up in an ordinary pulping machine. When this material is so pulped it is worked into and combined with the collodionised cotton cloth before described.—Patent completed.

1220 E. O. CATRIN, Paris. *Bottle cock.* Dated April 21, 1869.
This consists in the application of a key acting as a cock at the upper part of the bottle, the neck of which is traversed by an opening which receives the key.—Patent completed.

1221 B. PICARD, Ivry. *Towing.* Dated April 21, 1869.
The tug is constructed simply for carrying its fuel, mooring ropes, and spare stores, and constitutes the locomotive of the train, consisting of a number of vessels of a uniform and very light build, and greater in length than breadth, so as to draw as little water as possible, exceeding that of the tug only by a few inches. The tow chain is either wound by a windlass or is passed over pulleys arranged in an opening in the centre of the bottom of the tug, from whence it drops to the bed of the river, the point of action of the tractive power being the water level.—Patent abandoned.

1222 J. W. M'CARTER, Londonderry. *Condensers.* Dated April 21, 1869.
The condensation is effected by injecting cold water, and the condenser is made in two compartments. The exhaust pipe from the engine communicates with the top of the first compartment, and this has at its bottom an opening provided with a valve and leading into the second compartment, whilst the other has at its bottom an opening provided with a valve and leading into the waste pipe. The cold injection enters by a rose nozzle projecting into the upper part of the upper compartment. A lip or rim is formed round the opening between the two compartments, and serves to retain some water in the upper compartment, from which the supply for feeding the boiler is withdrawn by a pipe.—Patent completed.

1223 T. C. BULL, Weobley, Hereford. *Boots and shoes.* Dated April 21, 1869.
This consists in applying and attaching outside each of the usual pieces of elastic or side springs a protective piece of kid, leather, or other suitable material, according to the nature and strength of the boot or shoe.—Patent abandoned.

1224 M. HENRY, Fleet-street. *Pyrophosphate of lime.* Dated April 21, 1869.
Phosphoric acid when displaced or replaced in a cold state by certain acids in solution, will itself displace or replace these same acids when the solution has attained a temperature of 90deg. to 100deg. Centigrade. When desiccated under heat the operation becomes more complete. According to this invention this reaction is applied to a solution containing chloride of calcium and acid phosphate of lime. The solution is evaporated to dryness and a dry product is obtained, which, when taken after washing, yields a nearly insoluble phosphate of lime and chloride of calcium. The hydrochloric acid liberated by the operation is collected and concentrated to serve again.—Patent completed.

1225 H. C. MAYER, Craven-street, S.W. *Velocipedes.* Dated April 21, 1869.
This consists in attaching to one or two-wheel velocipedes, and to velocipedes generally when desired, an adjustable supplementary balance wheel or wheels, one or more of them for the purpose of steadying and guiding the velocipede when in use, and also when furnished with only one or two wheels the velocipede may stand of itself.—Patent abandoned.

1226 M. PLETTS, Newcastle-on-Tyne. *Oil feeders.* Dated April 21, 1869.
This consists in making the feeder or vessel of metal with a spout at an angle in the ordinary way, but having a prolongation of the spout or a tube in connection therewith within the vessel; this prolongated spout or tube is at an angle inclined to the bottom of the vessel and made of any size or shape, but preferably of the same capacity as the projecting spout (or nearly so), or so constructed

that it may be adjusted to varying capacities or charges by means of a movable diaphragm or stop, or by other suitable means furnished with suitable perforations to admit oil, and supplied with a ball valve, so that when the handle of the feeder is depressed and the spout raised, the ball falls to the end or bottom, or on the stop of the inner spout. When the latter becomes charged when elevated, the charge is delivered into the outer spout, where it is cut off by the ball valve, and thence to the part desired.—Patent abandoned.

1227 C. D. ABEL, Southampton-buildings. *Mural paintings.* (A communication.) Dated April 21, 1869.

The invention consists in the application of the processes of chromo-lithography for printing the requisite designs upon a paper, which serves subsequently as the medium for transferring the designs to the walls.—Patent completed.

1228 C. M. BARKER, Kennington Park-road. *Steam generators.* Dated April 21, 1869.

The boiler is constructed with an inner and outer shell connected together by an annular base plate. The inner shell, which is riveted to the annular base plate, forms the firebox; the space between it and the exterior shell, which is bolted to the base plate, contains the water and return descending flue tubes. The bolting of the exterior shell to the base plate is effected by means of ordinary bolts and nuts in combination with strengthening or washer plates of a length sufficient to receive three or more of the bolts. Between the junction surfaces of the shell and the annular base plate a seating of sheet lead enclosed in or lapped with copper wire gauze is interposed, the gauze preventing the lead from being pressed out under the pressure of steam or of the bolts.—Patent completed.

1229 W. JOHNSON, Elms, Sketty, Swansea. *Communication between passengers and guard.* Dated April 21, 1869.

The mechanical arrangement is contained in a small box, which can be readily attached to a carriage on the roof or flooring, and consists of two bell cranks placed close to each other somewhat in the form of the letter W, each crank having an upright tongue, to which a wire running from end to end of the carriage is firmly attached. The two central points of the crank support a small block, from which depends a cord passing into the compartment of the carriage. This cord is also connected with another wire running across the carriage at right angles with the one before mentioned, which works a semaphore on either or both sides of the carriage.—Patent abandoned.

1230 C. E. BROOMAN, Fleet-street. *Dressing fabrics.* (A communication.) Dated April 21, 1869.

This consists of one or several cylinders revolving with a rapidity more or less great, and provided with pin plates, combs, fallers, or similar appliances according to the effect desired to be produced acting against the fabric by means of centrifugal force. The pin plates or combs are attached to the cylinders by one of their ends only, the others being left free. As the fabric passes the cylinders these combs strike upon it through centrifugal force with a beating action. In this manner a very superior dressing is obtained.—Patent completed.

1231 W. ROBINSON, Tipton. *Thin sheets of metal.* Dated April 21, 1869.

This consists in manufacturing thin sheets of steel from bars, slabs, or other pieces of steel having on their opposite faces thin layers of wrought or malleable iron.—Patent completed.

1232 J. H. A. BLECKMANN, Solingen. *Firearms.* Dated April 21, 1869.

The breech of the arms constructed according to the invention is opened and closed by a piece worked by a lever or handle attached to the axis of the piece, and placed at the side of the firearm, instead of being actuated by the trigger or by a lever at or immediately near the trigger guard. This closure or closing piece comes against the chamber of the barrel when closing the breech, and it moves on an axis placed in a line or direction at right angles to the direction of the axis of the barrel. Its front edge comes below the level of the muzzle when the breech is opened.—Patent completed.

1233 J. FRANCIS, J. DONALDSON, and G. REAVELY, Galashiels. *Locking railway sidings.* Dated April 21, 1869.

In order to prevent the chock blocks by which the passage of waggons out of a siding on to the main line is checked from being removed by accident or design, the inventors employ apparatus so arranged that when the chock blocks have been placed over the rails, they can only be removed by the passage of an engine or waggon towards the siding, or at least by the use of great force much exceeding the power of one man. They mount the chock blocks on levers, which can move in a horizontal direction, and the blocks are formed by preference in such a manner that a truck in running over it to pass out of the siding would be thrown off the rails on to the ballast, and thus arrested in its onward course to the main line.—Patent abandoned.

1234 J. HOLDING, Manchester. *Looms.* Dated April 22, 1869.

The inventor adapts to the bracket of the "temple" a set screw for securing the "temple" to the "temple rod" on a line with the temple behind the rod, in contradistinction to placing such set screw underneath. By this arrangement the "set screw" is more readily got at for adjustment, and the cloth is kept closer to the top of the lathe.—Patent completed.

1235 G. DANIA, Rochdale, and J., T., R., and S. STOTT, Wardle. *Carding engines.* Dated April 22, 1869.

The inventors support the main cylinders on each side of the middle doffer in fixed bearings, and they support the axle of the middle doffer in bearings that are capable of being raised or lowered or moved laterally by regulating screws or other equivalents; by this arrangement, the piston of the middle doffer can be readily adjusted to the surface of the main cylinders.—Patent abandoned.

1236 H. T. LEWIS and W. WHITE, Handsworth. *Sash frames.* Dated April 22, 1869.

The apparatus by which the inventors carry this invention into effect consists, substantially, of a cog-wheel working on a fixed pin or axis and enclosed in a frame of suitable size and strength, which frame is fixed into the wall plate immediately opposite the bottom bar of the upper sash and the top bar of the lower sash. The side rail of a sufficient portion of the upper sash and a corresponding portion of the side rail of the lower sash is fitted with a rack to correspond with the cogs of the wheel, so that when the lower sash is raised, the upper sash is lowered in the same degree.—Patent abandoned.

1237 J. ECCLES, Black-lane, Radcliffe. *Lessing warps.* Dated April 22, 1869.

This consists principally of two metallic combs or open reeds attached to bars of wood, iron, or other suitable material, which are so hinged together that the points of the teeth of the combs or reeds may be either brought into close contact or separated a certain distance apart. The combs also are so arranged that the points of the teeth of one comb come opposite to the spaces between the teeth of the other and *vice versa*, so that when the combs are brought together, the yarn cannot enter the spaces between the teeth in either of the combs; each tooth, however, has cut in its extreme point a shallow notch sufficient to hold one thread.—Patent abandoned.

1238 G. WHITE, Queen-street, Cheapside. *Movable dam.* (A communication.) Dated April 22, 1869.

This consists of a ship, large boat, or other suitable vessel or hulk provided over the greater part of its length and middle of its width or beam with a longitudinal slit or furrow extending from and through the keel or bottom of the ship to the deck, which slit or furrow is open at the bottom and closed at the sides and top so as to prevent the water which enters freely from below into it from communication with the interior of the hulk or vessel. In the slit is situated a vertical partition, plate, or panel of wood, sheet iron, or other suitable material, which is to serve as a movable dam, and for this purpose may be set more or less inclined in the vertical plane by means of the horizontal trunnions or bolt working in bearings fixed to the kelson or other suitable part of the vessel. To the stern and to the bow are fixed pintles, in which are inserted piles provided at the lower end with an earth screw for screwing the piles in the bottom of the river, for fixing the hulk in any suitable angular position in respect to the current and allowing it to rise or to be immersed as found necessary.—Patent completed.

1239 W. CATCHPOOL, Goswell-road. *Treating straw.* Dated April 22, 1869.

The straw is first steamed, but this steaming separately is considered as not new, and when this has been effected the inventor compresses the fibre, by preference whilst in a heated state, in chambers of convenient form and size, where, by the action thereon of a suitable piston or plunger, it may be reduced into blocks of the form and to the extent desired. When this compression has been effected the fibre is removed from the chamber and allowed to cool, and it will then be found to retain the form given to it.—Protection refused.

1240 J. G. RIDLEY, Newcastle-on-Tyne. *Waste rails, tyres, &c.* Dated April 22, 1869.

The inventor takes crop ends of Bessemer or other similar steel rails, imperfect ingots, tyres, or any scrap of Bessemer steel or waste steel of a similar nature to that known as Bessemer's steel. He proposes, in the case of rail ends, to take them as they are cut at the rolling, to heat and to roll them into a flat bar or other convenient form for piling. He then takes the pieces and cuts them into suitable lengths for piling according to the nature of the required finished article, whether for plates, bars, angles, or other forms. He piles the pieces as closely as possible upon a slab of wrought-iron either formed of a plate or bar (whether puddled scrap or other iron or steel), and covers them with another slab of the same or a similar material.—Patent completed.

1241 M. HILLARY, Andover. *Harrows or drags.* Dated April 22, 1869.

It is proposed to effect a perfect tieing or trussing of the frames of harrows and drags by the aid of longitudinal bars either independent of the zig-zag beams and attached to cross bars or attached to the angles of the beams themselves. By passing these longitudinal bars alternately over and under the cross bars a doubly trussed frame is obtained.—Patent abandoned.

1242 G. G. TANDY, Anerley-road, S.W. *Carburetting air.* Dated April 22, 1869.

The improved apparatus for carburetting air or gas which forms the subject of this invention is divided into two parts consisting of an upper and lower chamber. The upper chamber contains the body of the liquid, and the lower one that portion which is being taken up by the gas or air passing through the chamber. The object of this arrangement is that the gas or air shall be uniformly impregnated with the liquid, which shall be expelled from time to time from the reservoir above.—Patent completed.

1243 A. BORGNET, Swansea. *Paris composition.* Dated April 22, 1869.

The metallic base which is employed in the manufacture of this improved composition or paint consists of globular zinc or grey oxide, otherwise known as "sweeps," and which is a product obtained in the smelting of zinc ores. This substance, in the form of an impalpable powder, is now mixed with boiled linseed oil in the proportion of 66 parts by weight of the grey oxide to 20 parts of the boiled oil. These substances intimately commingled make mixture No. 1. The inventor also makes a siccative mixture by treating raw linseed oil in the following manner. He takes oxide of manganese (in the natural state), say one part, and having broken it up to about the size of small peas, he boils it in (say) four parts by weight of raw linseed oil in an open vessel until the desired consistency is obtained. The manganese he encloses in a strong linen bag, and inserts the bag in a basket or perforated vessel of iron that will allow of the raw linseed oil coming into contact with the oxide of manganese through the bag. This basket he suspends in the oil so that it shall not touch the vessel containing it, and when the boiling is stopped he removes the basket and its contents from the vessel. By this treatment he obtains mixture No. 2. For a third mixture the inventor dissolves India-rubber, or other equivalent vegetable gum, in turpentine or other suitable solvent, the proportions being (say) two parts of the gum to seven parts of turpentine or other solvent. Of these several mixtures the inventor takes (say) 86 parts of No. 1, 5 parts of No. 2, and 9 parts of No. 3, and combines the same by stirring, or by any other proper means while cold, and when completely combined a liquid compound is formed suitable for the purposes of this invention.—Patent completed.

1244 A. BORGNET, Swansea. *Paint.* Dated April 22 1869.

This relates to the preparation of paint, and consists in the employment for that purpose of clays, by preference refractory clays known as fireclays, and more particularly the fireclays occurring in the basin of the river Meuse, in Belgium, and known as Belgian fireclay.—Patent abandoned.

1245 W. R. LAKE, Southampton-buildings, Chancery-lane. *Locks.* (A communication.) Dated April 22, 1869.

The locks to which this invention refers are what may be termed latch locks, as the bolt in each of these performs the duty of locking and of latching, and the general and leading characteristic of this series of locks consists in their having a latch or bolt that can be operated from one or both sides of the door by a knob or its equivalent, when the latch or bolt is not otherwise set or controlled by a key or its equivalent which turns a lever or eccentric hub in the lock, and disconnects the bolt or latch from the action of the knobs, and then the bolt is a locking bolt.—Patent completed.

1246 W. R. LAKE, Southampton-buildings, Chancery-lane. *Communicating in railway trains.* (A communication.) Dated April 22, 1869.

This system is composed of a shaft or axle placed above each carriage. This is supported in any convenient manner, and furnished with traction levers, which give it a rotating movement so as to actuate one of the detents or bent levers, which are fixed on its extremities. Each of these detent levers is bent to act upon the preceding detent, and they are furnished with adjustable balls or counterweights, which can be moved and regulated at pleasure.—Patent abandoned.

1247 W. PALLISER, Army and Navy Club, and T. ENGLISH, Wandsworth. *Armour plating.* Dated April 23, 1869.

This consists in the application of nuts having spherical bearing surfaces to bolts constructed in accordance with the invention for which Letters Patent were granted dated December 6, 1862 (No. 3,281). In employing these screw bolts, it is preferred to reduce the area of the shank by cutting the screw thread (by preference of a rounded form) along the entire length of the bolt, in which case, in place of the ordinary head of the bolt, the inventors provide a separate head or nut with spherical bearing surface screwed on to the end of the bolt. For the seat of such spherical nut or head, the inventors form a corresponding recess with spherical bottom surface in the armour plate, and, for the connection of the nut with the back of the structure, they either form a similar spherical recess in the bearing surface, or they interpose between this surface and the nut a washer having a spherical recess or seat for the nut.—Patent completed.

1248 N. WILSON, High Holborn. *Velocipedes.* Dated April 23, 1869.

The inventor arranges his velocipede so as to bring the legs of the rider into a more favourable position to propel either the forward or hindmost wheel or wheels, and also so arranges the crank movement and seating for the foot of the rider that he may drive on an independent shaft having a pinion thereon, such gearing to be either frictional or with teeth, which will work on the axis of the running wheel of the velocipede, there being a difference of diameters (say) of one-half or one third; so the rider can drive the velocipede up an incline with perfect ease.—Patent abandoned.

1249 G. WHITE, Queen-street, Cheapside. *Motive power.* Dated April 23, 1869.

This consists in causing a ball to circulate rapidly when set in motion by manual or other power in a circular channel provided in a trough, the centre of which latter is connected by a ball socket joint to a fixed circular bearing, the rim of which bearing limits the inclined positions which the trough assumes when, by the rapid circular motion of the ball in the above-mentioned channel, the trough yields to the motion of the ball in such manner that it causes the ball to act as if falling continuously down along an inclined plane, thus allowing the ball to gradually increase its velocity.—Patent abandoned.

1250 W. A. LYTTLE, Hammersmith. *Telegraph batteries.* Dated April 23, 1869.

When the cells of a battery are formed of earthenware the inventor does not glaze the pottery biscuit or have it glazed only on the outside. He renders it both non-conducting and proof against the chemical action of the battery liquids by heating the biscuit and filling it with, or immersing it in, boiling pitch, or other bituminous, fatty, or resinous substances. The earthenware is then drained, and when cold is ready for use.—Patent completed.

1251 G. T. BOUSFIELD, Brixton. *Sheep washing.* (A communication.) Dated April 23, 1869.

A close box or tank is employed which is supplied with water under pressure from a pump or elevated reservoir. The washing jet is connected with the bottom of this box or tank by two metal pipes, which are inserted into holes in the bottom and fixed by nuts screwed on from the inside.—Patent abandoned.

1252 S. SMITH, Derby. *Railway axle and axle boxes.* (A communication.) Dated April 23, 1869.

In the side of the axle-box nearest to the wheel the upper part is bevelled upwards towards the wheel and the lower part bevelled towards the interior of the box, so that should the lubricant in the upper part be thrown upwards by the revolution of the axle it would fall on the lower bevelled part, thus returning into the axle-box and saving all waste. In order further to ensure the prevention of any escape or waste of the lubricant a washer of sheet India-rubber protected at the bottom by an iron plate and at the top or upper part by a plate of zinc or other soft metal is placed on and secured to the outer side of the axle box.—Patent completed.

1253 W. B. DICK, Glasgow, Scotland. *Extinguishing fires.* Dated April 23, 1869.

This relates to the extinguishing of fires by means of a mixture of carbonic acid gas and water. The apparatus comprises a wheeled carriage, the body of which is in the form of a tank made with sheet iron fixed upon angle iron frames, and which is divided into three compartments. Pumps are fitted in two of the compartments and are arranged to be actuated by a beam on a rocking shaft, which is provided with the usual levers for the application of manual power.—Patent completed.

1254 J. WHITTAKER, Oldham. *Moulding wheels.* Dated April 23, 1869.

The machine consists of a foundation plate or frame, at the centre of which is a hollow stud or boss on which a table or face plate revolves which carries a worm wheel such as is used in the ordinary machine for cutting toothed wheels, and is furnished with a worm, and shaft,

and pinions in the same manner. On the table or face plate is placed and secured the moulding-box in which the mould is to be formed. At one side of the foundation plate or frame, and connected with it, is an upright pillar, at the top of which is a horizontal slide.—Patent com pleted.

1255 H. E. NEWTON, Chancery-lane. *Boilers.* (A communication.) Dated April 23, 1869.

The object is to prevent steam boilers from bursting, and the invention consists in the use of a hollow metal cylinder with a valve seat in its head, connected and communicating with a tube extending to the bottom of the boiler. A valve is placed in this cylinder, and consists of a metal spindle and piston (made by preference hollow), and on the spindle above the piston is a projecting bulb or cone.—Patent abandoned.

1256 H E. NEWTON, Chancery-lane. *Puddling iron* A communication.) Dated April 23, 1869.

This consists in reducing the cast iron to coarse granules or pieces, so that they may melt down more quickly than pigs into a fluid state. Granules or pieces varying in bulk from spheres of about 2-10th of an inch to 1in. in diameter, with a small portion larger and smaller than these limits, have been found in practice to work satisfactorily. Care must be taken, however, not to make too large a proportion of fine granules, as in that case they would quickly be decarbonised and rendered infusible, and thus prevented from melting and mixing in a liquid condition with the liquid iron oxide. Such a mixture of the iron (in a liquid state) with the liquid oxide is indispensable to the complete success of the process.—Patent completed.

1257 T. WILSON, Birmingham. *Cartridges.* Dated April 23, 1869.

This consists in constructing cartridge cases by taking a plain metal tube closed at one end for the reception of the powder, and forming separately a rim, and afterwards attaching it to the closed end of the tube either by brazing, sol lering, or otherwise.—Patent abandoned.

1258 E. TATHAM, Nottingham. *Levers and nebs.* Dated April 23, 1869.

This relates, first, to the construction of levers or bars, and consists in making or fitting them with two pins or wires, so that the thread or threads may enter between them when the levers are acted upon or depressed by the motion of the "jacquard." The pins or wires are slightly spread outwards at the bottom to facilitate the entry of the threads. It consists, second, in the construction of "nebs" or thread carriers; they are made with two points, and are employed for dividing the threads when lifted by the mechanism. In this position, the needles are moved towards and passed through between the nebs. On the needles retiring, the nebs are lowered and the threads are laid on the needles.—Patent completed.

1259 E. M. REILLY, New Oxford-street. *Explosive bullets.* Dated April 23, 1869.

The objects are, first, in the construction of explosive bullets, which will by the force of the explosion break into a certain number of pieces according to the formation or shape of the interior of the bullet; and, second, the construction of an improved socket or ring in which the percussion or other explosive medium is placed.—Patent abandoned.

1260 J. MAJOR and W. WRIGHT, Swallow-street, and G. H. JONES, Alpha-road. *White lead.* Dated April 24, 1869.

This consists in the manufacture of white lead in a closed chamber or chambers heated artificially without the employment of spent tan or such like fermenting materials, or earthenware pots, as in the methods now in use. The necessary vapour or vapours and gas or gases, for instance, watery vapour, ammoniacal vapour, acetic acid vapour, pyroligneous acid vapour, hydrochloric acid gas, and carbonic acid gas, which may be provided in any convenient manner, are fed into and through the chamber or chambers containing the lead or compounds to be converted into white lead, these vapours and gases being properly regulated during their course through the same in any convenient manner.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated November 2, 1869.

3173 C. G. Gumpel, Leicester-square. Improvements in ships' rudders and in steering gear therefor.

3174 R. Spice, Cirencester-place, Fitzroy-square. Improvements in the manufacture of artificial stone, and for forcing liquids into porous substances.

3175 G. White, Queen-street, Cheapside, City. An improved metallic central-fire cartridge for breech-loading firearms.

3176 R. Davies, Liverpool. Improvements in mechanism or machinery for transmitting motive power.

3177 W. Connell, Glasgow. Improvements in water-closets.

3178 A. H. Brandon, Rue Gaillon, Paris. Improvements in motive-power engines, and in the means and mechanism for generating such power.

3179 A. Wyllie, Stewarton, Ayrshire. Improvements in the manufacture of Scotch bonnets, and in the material, means, and apparatus employed therefor.

3180 C. E. Cav...y and J. Newton, Manchester. Improvements in tramways, and in carriages to run thereon.

3181 J. P. Hawley and E. E. Hill, Brixton, Surrey. Improvements in apparatus for controlling the flow of water from constant supply pipes.

Dated November 3, 1869.

3182 S. Leoni. St. Paul-street, New North-road. Improvements in apparatus for cooking and lighting by gas.

3183 A. Grothe, Strand. Improvements in apparatus for registering the number of passengers travelling in or on public conveyances.

3184 T. Wright and I. Fox, Nottingham. Improvements in machinery or apparatus employed in the manufacture or production of piles on net or lace or other fabric made on twist lace machines.

3185 F. F. Samier, Rue du Boulois, Paris, and A. Antholne, Rue Corbeau, Paris. Improvements in metallic vessels intended to prevent all liquid or solid inflammable substances from igniting.

3186 H. J. H. King, Glasgow. Improvements in apparatus for measuring, indicating, and regulating the flow or passage of liquids.

3187 T. S. Martin, Plymouth. Improvements in the construction of self-acting stopcocks.

3188 M. L. Winn, San Francisco, California, U.S.A. An improved apparatus for shampooing and washing the head.

3189 N. W. Blanchard, Dutch Flat, California, U.S.A. An improved substitute for curled hair for upholstering and other purposes, and process employed in the manufacture thereof.

3190 E. Snell, City-road. Improved compounds or compositions in imitation of marble, veneer, and other substances to be used in the manufacture of fancy and other articles.

3191 J. M'Dowall, Johnstone, Renfrewshire. Improvements in machinery for sawing and otherwise cutting timber.

3192 W. Gardner, Manchester. Improvements in mechanism or tools for the manufacture of parts of watches or timekeepers, and in the mode of securing the works of watches in their cases.

3193 G. Sinclair, Leith, Edinburgh. Improvements in treating wood and other vegetable fibrous materials for the production of paper pulp, and in the boilers and apparatus employed therefor.

3194 E. Finch, Beaufort-square, Chepstow, Monmouthshire. Improvements in dock gates and caissons for closing the entrances to docks and basins.

Dated November 4, 1869.

3195 J. Booth, Broomhill, Sheffield. Improvements in the modes of rolling or reducing metal, and in the arrangement of machinery for effecting such rolling or reducing.

3196 H. Wilde, Manchester. Improvements in the construction and working of electric telegraphs.

3197 W. E. Gedge, Wellington-street, Strand. A novel vehicle termed the three-wheeled velocimane.

3198 M. Wilson, Wellington-street, Southwark. Improvements in sink traps.

3199 S. Rusk, Pancras-lane. Improvements in bar iron for the manufacture of shoes for horses and other animals.

3200 C. de V. Wells, Marseilles, France. An improvement for regulating the speed of marine steam engines when the screw is lifted out of the water.

3201 F. Armstrong, Paris. Improvements in sewing machines.

3202 A. Russell, Cheapside. Improvements in apparatus for making tucks or plaits applicable to sewing machines.

3203 E. Edmonds, Rockville, Paignton, Devonshire. An improved coffeepot and filler for the same.

Dated November 5, 1869.

3204 C. Crookford, Holywell, Flintshire. Improved modes of treating metallic ores and materials and obtaining metallic and chemical products therefrom, and for utilising some of the waste products from smelting works, chemical works, tin plate works, galvanising works, and paper mills, and for improvements in furnaces and apparatus in carrying out the same.

3205 J. Maiden, Oldham. Improvements in lubricators.

3206 J. M. Stanley, Sheffield. Improvements in furnaces and crucibles for melting steel and other metals, and in furnaces for heating steel and iron.

3207 J. Turnbull, Glasgow. Improved cut-off gears for steam engines.

3208 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in sewing machine needles.

3209 J. K. Northall, Netherton, Worcestershire. Improvements in apparatus or machinery for welding and finishing tubes.

3210 F. Pash, Gracechurch-street, City. The improvement of the construction of bicycles or velocipedes.

3211 A. M. Clark, Chancery-lane. Improvements in boring tools.

3212 R. Douglas and L. Grant, Kirkcaldy, Fifeshire. Improvements in motive power engines.

Dated November 6, 1869.

3213 F. Taylor, Nottingham. Improvements in sewing and embroidering machines.

3214 H. Livesey, Greenbank, Blackburn. Improvements in polycycle rings or circular velocipedes.

3215 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of, and devices for, securing stair rods.

Dated November 8, 1868.

3216 P. and A. Walker, Brougham-road, Dalston. An improved gas meter.

3217 T. Perkins, Hitchin, Hertfordshire. Improvements in apparatus for ploughing or cultivating land.

3218 N. Shaw, Eau Claire, Wisconsin, U.S.A. Generating steam in steam boilers, and protecting the gratebars in the furnaces under the said boilers.

3219 J. C. Heywood, Royal Hotel, City. Improvements in weighing machines or scales.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, NOVEMBER 19, 1869.

LONG SPAN BRIDGES.

AN allusion was made in our leading article of last week to the fact that engineers are not so prone to indulge in the erection of bridges of large spans as was the practice some years ago. Experience has since demonstrated that when the bearings between the piers reach a certain dimension, the superstructure becomes more expensive than the substructure. It is not generally known that but for the fear of introducing an awkward curve in the line, the bridge over the Menai Straits might have occupied the site of the Swilly instead of the Britannia Rock, and its present maximum spans would have been reduced by nearly 100ft. But the engineers of the old school had a mortal dread of steep gradients and sharp curves, and considered their absence cheaply purchased by any other sacrifice incurred in the shape of embankments, cuttings, tunnels, bridges, and permanent works of any description. With their limited ideas of one mile radius for the curves, and one in a hundred for the gradients, what would they have thought of engines being manufactured and almost able to "turn in their own length?" and as for gradients, "going up a ladder" is a mild expression for their climbing capabilities! As with the largest span bridge in England so with that in the sister country. The Boyne Viaduct has a maximum span of 260ft., and carries the Dublin and Drogheda Railway over the valley of that river at some distance from the town. It is now well understood that there was not the slightest necessity for erecting so expensive a bridge, and that the line could have been taken, to more advantage in every sense, nearer the town, where the valley narrows.

There is no disguising the truth that when iron was introduced as a material eminently adapted for the construction of some of the most prominent of the permanent works of a railway, there was a pardonable rivalry among the members of the profession with respect to erecting bridges of large span. Telford led the way both at home and abroad; Stephenson and Brunel followed, and Fairbairn and others brought up the rear. It is clear that every engineer considered it incumbent upon him to prove what he could do with iron, and many structures of that material, hideous in appearance, with proportions in mockery of science, and a distribution of metal betraying an utter and reckless ignorance of the knowledge of strains and strength of materials, attest to the present day the manner in which some of the profession displayed their ability. To such a pitch did their incompetency attain that, after many fatal proofs of it, a Royal Commission was appointed to inquire into the "Application of iron to railway structures." The whole subject was then thoroughly sifted, the aid of the mathematician was called in to supplement that of the engineer, and the result was the establishment of certain laws and regulations which, if they could not instruct the ignorant, could, at any rate, protect the public from the consequences of their ignorance.

Admitting that bridges of large spans have been erected in positions in which it has been subsequently demonstrated there was no absolute necessity for them to occupy, it must not be understood, on the other hand, that the necessity for a bridge of large span may not arise. There are manifestly numerous localities which roads and railways are ultimately destined to traverse possessing physical features incapable of being surmounted by any other means. To be of any value, railway intercommunication between any two points must be continuous. The chain must be perfect. The absence of one link is fatal to the whole. Should a ravine, a mountain pass, a chasm, or a hiatus of any kind intervene along the route, it must be bridged, and the size of the span must obviously depend upon the number of piers or supports that it is possible to erect on the sides and bottom of the gulf. This brings us to the question of the maximum span that it is possible to obtain by any known principle of scientific construction, and just at the present time it has a peculiar interest bearing upon the proposed international bridge over the Channel. We are not about to advocate any particular scheme or discuss the merits of any proposed method for accomplishing the transit between the two shores. Our readers will find full information upon this point in a paper published in our recent numbers.* The only method to which our article has any reference is that of M. Boutet, but were we inclined to advocate the project, we have not the slightest evidence which would enable us to form any opinion of its theoretical or practical feasibility. In the following investigation no notice will be made of stone arches, as their maximum span does not exceed 200ft., although that principle, being the oldest, has the first claim to consideration. It was, in fact, the original principle proposed by Stephenson upon which to execute the bridging of the Menai Straits. There is no necessity to refer to the reasons why that design was abandoned, because it had to do with other considerations, which reflected not the shadow of doubt respecting the practicability of the project. Neither is there any necessity for our present purpose to advert to the scheme in detail. It is sufficient to state that the maximum span in cast iron was 360ft. So far as theoretical construction is concerned there is no limit to the span of an arch or suspension bridge, but, in spite of this, the former type has almost become obsolete for spans exceeding 200ft., and the latter has never yet been successfully applied to railway traffic. By railway traffic we do not mean the drawing of carriages, or the crawling of a locomotive, over a bridge, but the passage of an express train or limited mail, at full speed. Here we notice the difference between theory and practice. Stephenson considered that if he increased his cast-iron arch to a span of 460ft., as he contemplated, the rise of the crown due to expansion and contraction would present a difficulty that he would be unable to provide for. This was no doubt an erroneous impression, as he would have found had not the contingencies imposed by the Admiralty compelled him to abandon the arch principle altogether, and seek for a solution of the novel engineering problem in the adoption of different means. Without inquiring into the relative suitability of cast and wrought iron for the construction of arches, it may be taken for granted that 500ft. will represent the practical limit to the span of an iron arch.

The next type that deserves consideration is that in which the horizontal strains are resisted by the various members of the structure itself, and a vertical pressure alone transmitted to the supports; and the Menai Bridge certainly ought to be mentioned first. The question therefore is, what is the limit to the span of a tubular bridge? All bridges which are self-containing with respect to the strains exerted upon them come under the denomination of beams, and the limit of their spans is based upon the fact that the strength is as the square, and the weight as the cube of their lineal dimensions. The weight of a tubular or any solid-sided girder increases far more rapidly with an increase of span than that of the lattice or open web type, in consequence of the large amount of metal required as stiffening irons. About 21 per cent. of the whole material in the Menai Bridge was absorbed in stiffening the sides. The question of determining the maximum possible span of girders becomes very complicated, because by the employment of steel instead of iron much larger spans could be obtained. At the same time there are no practical examples upon which to base a reliable calculation. It will be safer, then, in the present instance to deduce our conclusions from what has been already accomplished with a material that is trustworthy than to hazard conjectures respecting what might be done with another that has not yet been tried. The ultimate span reached by steel would not probably exceed that attained by iron by more than 30 per cent. A tubular girder would not practically exceed the limit of 600ft. as the maximum span, and if of steel, might reach 800ft. There is very little doubt that, with the exception of Dr. Fairbairn, the great advocate for solid-sided girders, no engineer would ever again employ the tubular system. A glance at the recently erected railway bridges of large spans points out unmistakably that the open web principle has superseded the older and the more cumbrous one. Larger spans would be practicable upon the open web or lattice principle than upon that of its predecessor. A lattice girder would probably reach a span of 800ft. if constructed of iron, and of 1,000ft. if steel were employed. Whatever particular form of horizontal girder might be adopted, it may be safely laid down that the maximum span attainable with any material would not be less than 1,000ft., or, in round numbers, the fifth part of a mile. It must not be considered that we are advocating the economy of bridges of five spans to a mile; we are simply demonstrating their possibility.

The only system to be now alluded to is the suspension, which, so far as mere length of span is concerned, decidedly occupies the first place. Arguing analogically from the size of the existing spans of suspension and horizontal girders, and calculating proportionally, the limit to the span of a suspension girder would be 1,700ft. The maximum limit, under any circumstances, might be put at 2,000ft., or about double that attainable by the other type of bridge. Besides these ordinary principles of construction there are others, such as those of Von Rupert, M. Boutet, and other engineers. With respect to these it should be borne in mind that while on the one hand there are unfortunately no practical data to be guided by, yet there is no valid reason why it may not be possible to achieve larger spans than have hitherto been attempted. The proper line of argument to adopt, and method of testing any of these novel schemes to be employed, is to follow the plan pursued in the case of the Britannia Bridge. Those who believe in the practicability of spans of nearly a mile in length should have a model constructed to an actual reduced scale of the bridge which is to serve the purpose. It should be broken, put together, and broken again, until the best proportions were thus experimentally arrived at. Calculations of the breaking weight and the strains upon the various parts could thus be accurately worked out, and the truth of theoretical formulæ either verified by empirical results or modified as might be necessary. This is the only plan by which to satisfy professional men and judges of such matters. The mere drawing of a design upon paper, and the results of mathematical investigations alone, are not sufficient to justify any confidence in a novel principle of engineering construction.

* *Vide* the paper "International Communication," by PERRY F. NURSEY, read before the Society of Engineers and published in the MECHANICS' MAGAZINE of October 22 and 29.

THE BOILER EXPLOSION ON BOARD THE "THISTLE."

SINCE our last notice of the lamentable occurrence on board the "Thistle," the coroner's inquiry has been concluded. A verdict was returned to the effect that the deceased persons came to their deaths by an accident caused by the escape of steam from the fracture of the crown of the furnace of the steam boiler, resulting from overheating, occasioned by a deficiency of water. The jury add that there is no evidence to show the cause of such deficiency. The jury were also of opinion that the boiler was well constructed and of proper materials. This verdict was based upon evidence given by several gentlemen eminently qualified to deal with the question, but who one and all failed to account absolutely and precisely for the insufficiency of water. Let us glance at the evidence given upon the occasion. Mr. Williamson, the chief inspector of machinery afloat, stated that he had carefully examined the defects in the boiler, with all the mountings attached thereto, and was of opinion that from its general appearance the boiler had been short of water, whether from the feed-cock not being kept sufficiently open, or from excessive priming, he was not able to say. Mr. Scorer was the engineer officer in charge of the boilers, and it was his duty to see that the feed-cocks were kept in proper order, and he had with him in the stoke-hole a first-class petty officer to assist him. There was an indicator, marked with four degrees, to show how far the feed-cock is open, and Mr. Williamson had examined the cock and found that it was one degree open. The other two boilers, which were not at all injured, had only the same opening of the feed-cock, and they were sufficiently supplied with water. Mr. Williamson further stated that he did not think it possible that either a deficiency of water or priming could arise without it being indicated to those in the stoke-hole. Mr. Andrew Murray, C.B., surveyor of factories and consulting engineer to the Admiralty, also gave evidence tending to confirm that given by Mr. Williamson, adding also that the officers and men employed on these trials were so accustomed to them that they had lost all feeling of racing or extreme excitement which would induce them to do anything to incur any risk.

Evidence of a thoroughly independent character was given by Mr. L. E. Fletcher, the engineer to the Manchester Steam Users' Association, who had examined the ruptured boiler. His conclusion was that the explosion did not result from excessive or improper pressure of steam; neither did it result from any defect in the original construction of the boiler, or from any defect in its condition at the moment of fracture; but that it arose solely from the overheating of the furnace crowns, in consequence of which the plates composing them lost their strength, and, being unable to resist the pressure of steam, bulged down at the ordinary working pressure; the left-hand one rending transversely for a length of about 18in., and 2¾in. at the widest part, thus forming an opening through which the steam and hot water rushed out of the boiler, and playing into the engine-room scalded to death the men engaged there. As to the cause of the overheating of the furnace crowns, he had come to the conclusion that the water supply had been overlooked, and thus allowed to run short, when overheating would be inevitable—so that this explosion seems to have been due simply to shortness of water. Mr. Fletcher added that he had met with numerous cases in which furnace crowns had been injured though certainly covered with an ample supply of water; while, in one case, a rupture resulted very similar to that in the boiler under consideration. He could not in this case give any grounds for the shortness, further than by supposing it to have been an oversight.

With respect to the character of the boiler itself we have the evidence of Mr. John Boffey, foreman of boilermakers at Portsmouth. The boiler in question was made under his superintendence at Sheerness. The outside diameter was 6ft. 1in.; the furnaces were 2ft. 4½in. in diameter; the casing or shell was half an inch thick. The plates for the shell were supplied by contract from Messrs. Moser and Son's. The plates for the furnace were from Messrs. Cooper's, and were made with the best Yorkshire iron. The tubes were supplied by Russell and Son. The length of the boiler was 16ft. and half an inch, and of the tubes 6ft. and half an inch. On the completion of the boiler it was subjected to hydraulic pressure to the extent of 180lb. to the inch. The boiler in question was made expressly for the "Thistle," and was sent to her at Woolwich to be fitted in her. By the rules of the service the boilers, after being fitted, would be subjected to a similar test to that made on their completion. The furnaces were made of Cooper's best Yorkshire iron, tested in the Government establishments before being accepted from the contractor. It was tested by hot and cold test. The combustion chamber was of the same description of iron, and the tubes the same, and also the fronts of the boilers. The whole of the materials were subjected to the same test, and everything stood the test satisfactorily. This witness attributed the cause of the fracture to the top of the furnaces becoming red hot from want of water, and thus the strength of the boiler became completely destroyed. Other witnesses were called whose testimony was simply confirmatory of that already noticed, and whose conclusions were invariably to the effect that the accident occurred through shortness of water.

Looking at the whole of the evidence we cannot see how any other verdict could have been given by the jury. The witnesses were unanimous in their conclusions that the water level had been allowed to get too low, so that the plates had become weakened, and ultimately gave way under the pressure of the steam. The latter clause of the verdict, based as it was upon satisfactory evidence as to the soundness of the boiler, disposes of the contingency of overstrained economy to which we alluded in passing last week. But there still remains the mystery to which we then also alluded, and which will probably never be cleared up, and that is, how with a new and well made boiler, attended by a picked staff of engineers, such a catastrophe could have occurred. There is a possibility that the accident was due to a deposit of salt having taken place on the plates, and which might have been prevented by frequent blowing off. But those witnesses who examined the collapsed boiler make no allusion whatever to any appearance which would warrant this conclusion, so that we have not this hypothesis to fall back upon. Mr. Fletcher, however, seems to have had some idea of the kind in his mind when he referred to cases in which furnace crowns had been injured although covered with water at the time. Here such a condition is dimly hinted at. If a deposit of salt really took place, then there is no mystery whatever attached to the occurrence, which would follow almost as a matter of course. Independently of this, the mystery still remains. The evidence taken at the inquest does not throw any sufficient light upon the occurrence to enable us to state definitively and exactly what led to the rupture. The circumstances, however, point to the inevitable conclusion that an oversight had been committed by one or other of those who have unhappily paid the sad forfeit of their lives. Inconceivable as this may appear with men of thorough training and high character, yet such seems to be the only solution offered to the problem. It is one of those circumstances which occasionally arise to prove that man is not infallible.

THE HOLBORN VIADUCT.

THOSE who consider that a bridge over a public thoroughfare ought not to consist of one big hole and two little ones, would probably regard it as a very fortunate circumstance if it should become necessary to remove the structure of that description which has recently been permitted to encumber one of the widest streets in the metropolis. This is not the fault of the designer, but of those who selected and approved the design. It is not impossible that the City authorities, foreseeing, with that wonderful acumen which is ever characteristic of their operations, that some day or other Temple Bar must be removed, conceived the brilliant idea of perpetuating its obstructive features in another locality. It is acknowledged universally to be an intolerable nuisance in Fleet-street, but they may have consoled themselves with the reflection that it might be tolerable, at least for their time, in Farringdon-street. But behold how the Nemesis which watches over the interests of the traffic of a great city revenges herself upon those who violate her laws! The splintered bases and the cracked columns attest the measure of her wrath. Had the whole street been spanned by a single arch, as it should have been, there would have been no columns to splinter, no bases to shatter. Solid abutments would have withstood the thrust of the worst designed arch in the world, and if any columns had constituted a portion of the design, they would have been of a purely ornamental character, and not subjected to the action of strains which they were totally unfit to encounter. We have not, however, to do with the question of what might have been the best design, but with the present design, and more particularly with its present unfortunate condition. Many and ingenious have been the attempts to account for the position in which it is now placed. Enormous pressure, tremendous vibration, sinking of the foundations in consequence of a landslip, brittleness of the material of which the columns are composed, and many others more ingenious but less possible. In fact, the ingenuity of the cause alleged is always in the inverse ratio of its probability. There is no doubt that the traffic over the Viaduct is of a heavy, it may be said, of the heaviest description belonging to roads and streets, but still it is nothing in comparison with locomotive traffic. A bridge very similar in many features to that under consideration carries the South-Western Railway over the South Lambeth-road, close to the Vauxhall Station. The span is about the same, and the angle of skew also, but the two side passages for the foot-paths are spanned, not by small cast-iron, but by brick arches faced with stone. This bridge has been doing duty ever since the formation of the line some fifteen or twenty years ago, exposed to a very heavy rolling load, but it evinces no signs of deterioration or decay. And yet, when the City authorities repeat the experiment on a smaller scale, the result is partial demolition.

The plea of vibration sounds plausible enough, but it is more specious than real. Its effect does not depend, as might be imagined, upon the absolute amount of the rolling load traversing a bridge, but upon the relative proportion existing between that load and the insistent weight of the bridge itself. From the very nature of its construction, Holborn Viaduct bridge is a heavy bridge, and possesses a considerable insistent weight, which has a tendency to destroy any vibration that the passage of heavy traffic would give rise to. It would have been a great deal better for the columns if the superstructure had been made of wrought instead of cast iron, and the massive scrollwork spandrels replaced by light wrought-iron bracings. Unquestionably the cause which must have been most acceptable to Mr. Haywood, and to which the accident has been

attributed, is that which traces all the evil to a landslip. This is very difficult to believe, especially when it is borne in mind that the valley of the Fleet must have become tolerably well consolidated after centuries of traffic. If this were so, why should the effect be confined solely to the bridge? Why are not the foundations of the newly-erected adjoining buildings also affected? It would be almost too much to expect that the sinking should take place only under the Viaduct, although it is the lowest point in the valley. The danger of any settlement in the foundations requires to be especially guarded against where the principle of construction adopted is that of the arch. With a horizontal girder, a settlement that would be fatal to an arch would be productive of no evil effect beyond raising or lowering one end more than the other. The appearance of the structure might not be improved, but the evil would end there. This difference arises from the fact that in the horizontal girder there is no external force developed, except a direct vertical pressure on the supports, whereas in the arch the thrust exerted requires a perfectly unyielding and rigid support. The least settlement of one of them would cause such a derangement of the normal state of the equilibrium of the erection that it would be impossible to tell where the mischief would end.

Admitting the fact that the pillars, from their enormous and disproportionate lateral dimensions, are fully capable of carrying almost any pressure placed uniformly upon them, yet the case assumes a different aspect when the pressure is not placed uniformly upon them. The strength of a pillar when the pressure does not pass through, or nearly through, its longitudinal axis is reduced to one-third of what it is when the line of pressure and the axial line coincide. There are no two opinions about the inequality of the pressure brought upon the columns of the Holborn Bridge. The great difference in the dimensions of the centre and side spans fully corroborates that fact; and from the present visible heeling over of those that are splintered, it is equally manifest that the line of their geometrical axis does not by any means coincide with the line of pressure. Whatever, therefore, may have been their originally calculated strength, if any such calculation were ever made, that strength is now only one-third of what it was—a reduction which cannot be viewed without feelings of grave concern, not to say, apprehension. However large a margin may be left for contingencies, and in brick and stone the margin is frequently almost unlimited, yet when that margin is reduced to a third, it is time to examine very closely into what remains. It is very probable that the expansion and contraction of the metal has played an important part in conducing to the present state of the bridge, but to whatever source it may be traced it is absolutely due to the non-conversion of the external forces exerted by the arch into a uniform vertical pressure coinciding with the longitudinal axis of the columns. In other words, the theoretical conditions governing the stability and equilibrium of columns have been violated, and "hinc illæ lachrymæ." It has been suggested by a contemporary that the skewbacks of the piers should be set upon rollers, which in their turn would rest upon the top of the columns. This would be similar to the arrangement provided for the expansion and contraction of horizontal girders of large span, but there is no necessity for it in the case of iron arches. Their expansion amounts to a simple rising and falling of the crown, and with a properly designed arch, in which it is free to act in this manner, no evil consequences can possibly ensue. But if the arch be not free to follow such a course, it will, in its efforts to accomplish it, produce results similar to those now before us. It is said that "in the multitude of counsellors there is wisdom," and therefore, relying upon the truth of that proverb, we may expect to hear something very sagacious from the report that is in preparation by the gentlemen appointed to investigate the matter. At the same time, we do not expect anything very new or startling, as the subject has been thoroughly well sifted in all its bearings. Our enemies might, unfortunately, truthfully remark, that in London it takes one engineer to make a bridge, and three to mend it.

THE DAW CARTRIDGE SEIZURE.

IT will doubtless be well within the recollection of our readers that in the month of September, 1868, Mr. Daw, the gun and cartridge maker, of Threadneedle-street, was summoned before the Lord Mayor Allen for manufacturing cartridges within 100 yards of dwelling-houses without a licence, for keeping in store cartridges containing more than 5lb. of gunpowder, for not having a brick or stone magazine for the storage of the gunpowder, and, lastly, for having more than 200lb. of gunpowder in the house at one time. These allegations were made under the Gunpowder Act, which it was declared Mr. Daw had contravened. Notwithstanding that it was shown that the maximum of safety was ensured by Mr. Daw's arrangements, which were very perfect, and notwithstanding that it was shown to be the universal practice of gunmakers to fill cartridges very largely, the Lord Mayor convicted and imposed the full penalties, amounting to £40. Upon this conviction, and seeing that he had been singled out from amongst other manufacturers who were doing the same thing and were left unnoticed, Mr. Daw, through his counsel, obtained leave to state a case by way of appeal from the decision of the bench. This appeal came on for hearing last Saturday, when, as will be seen from our legal summary, the Court of Queen's Bench affirmed the convictions. This decision is of great importance to the gun and cartridge trade, inasmuch as every dealer in gunpowder filling cartridges upon his own premises is liable to £10 penalties, upon four counts, for the one operation performed on the same day, viz.:—Firstly, for unlawfully manufacturing ammunition without a licence. Secondly, for unlawfully keeping certain ammunition, to wit, a quantity of cartridges, containing upwards of 5lb. of gunpowder, in an unlicensed place. Thirdly, for unlawfully filling and charging ammunition in a building at a distance less than 20 yards from any other workshop on his own premises. And, lastly, for not having a magazine built of brick or stone for receiving and safely keeping the gunpowder used for the cartridges.

Now the question at issue turns upon the construction to be put upon the 18th clause of chapter 139 of the Act of Parliament 23rd and 24th Victoria, under which the right of gunmakers to fill cartridges exists. It has always been believed in the trade that the liberty of making up cartridges is permissible under this Act, and this belief has been universally acted upon. And we ourselves concur in this belief, subject of course to the degree of safety ensured, which in the present case was in excess of that enjoyed by other makers, inasmuch as Mr. Daw's cartridges, for which the Government had awarded him their premium, are especially safe. However, as a matter of fact Mr. Daw appears to have offended—however unwittingly—against the Gunpowder Act, and as a matter of law he was convicted and fined to the full extent allowed by the law. The proceeding which selected him from amongst many others appears to us to have been harsh and arbitrary, and the infliction by the Lord Mayor of four penalties for what is apparently but one offence certainly merits the expression of "hardship" which we understand was applied by the Court of Queen's Bench to the circumstance. Nevertheless, as the decision was legal, the Court had no alternative but to affirm it. From this decision let all engaged in this trade take warning, for, although they have been carrying on their business during the ten years since the passing of the Act without a single case of official interruption, and although no one has been interfered with during the fourteen months which have elapsed since Mr. Daw was thus visited, they know not how soon they may be. With the present reading of the Act in question, they will know what to expect should they be disturbed in a proceeding which they have hitherto believed to be perfectly permissible.

TELEGRAPHIC NOTES.

A GENERAL meeting of the Société du Cable Transatlantique Français was held on Wednesday, at which a report was presented by the directors. This document states that since the meeting on the 8th December last the cables of the company between Brest and St. Pierre and St. Pierre and Duxbury have been successfully submerged by the Telegraph Construction and Maintenance Company along the course judiciously laid down by Sir James Anderson, who accompanied the expedition. No better evidence of the careful navigation of the "Great Eastern" by her experienced commander, Captain Halpin, can be given, than the fact that the distance run on this occasion by the vessel differs only by four knots from the length of the course as laid down on the chart. The cables are in excellent electrical condition, their insulation has materially improved, and the practical working of them sustains no detriment whatever from the minute defect stated to exist on the section between Brest and St. Pierre. The arrangements made by the British Government for taking over the telegraphs throughout the country on the 1st January next cannot fail to be productive of benefit to this company by opening to it many stations where at present existing treaties with the older cable company exclude it from any portion of the traffic. By the introduction of this enterprise, the cost of a transatlantic message has been reduced to £1 10s., a rate which the directors believe will prove the mean between a judicious consideration for the public and the largest remuneration for the shareholders. The directors feel that it is a subject of congratulation that within the short space of twelve months an enterprise of such magnitude has been successfully carried through the several stages of raising the large amount of capital required, manufacturing and finally submerging the longest cable yet laid; and they feel that the especial thanks of the members are due to the Telegraph Construction and Maintenance Company for the unflagging energy and loyalty displayed by them and their officials in the execution of their important share in this truly international work. The company is also under obligations to the British and French Governments for the aid they have given the undertakings through their dockyards and officers, amongst whom may be mentioned Captain Richards, R.N., hydrographer of the British navy, and Capitaine de Rougeux, of the Imperial marine. The zeal displayed by the officials of the company merits also especial acknowledgment, which is accorded to them by the directors in the report.

Desks for writing telegrams are about to be placed in the lobby of the Cambridge Post-office, which will be enlarged for that purpose. The work of connecting the telegraph wires with the Post-office at Huntingdon is being proceeded with. They will cross the market-place from the summit of the Falcon Inn. The Post-office authorities have taken a house in Guildhall-street, Lincoln, for the purpose of converting it into a telegraph office. Preparations are being made for the impending change at Alford, Lincolnshire, posts being in course of erection between the Post-office and the railway station. The Stamford town council has granted permission for the erection of posts and wires from the railway station to the Post-office in St. Mary's-street, in that town. Mr.

E. Yates has visited Boston for the purpose of making the necessary arrangements in that town.

There is a report current that the Chancellor of the Exchequer will be able to arrange the money necessary for the purchase of the telegraphs without appealing to the general market. If this should in reality prove the case the effect must be encouraging, and the tendency in the rates of discount will again be towards decline. The operators would be glad to be definitively informed on the subject, since this is one of the causes influencing the prices of Government securities.

The directors of the Telegraph Construction and Maintenance Company have decided to convene a special general meeting of the shareholders at the end of the month, to authorise the return of £8 per share of the capital—£4 to be paid this year, and the balance as early as practicable.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

ANTI-CHOLERA TISSUE—PETROLEUM FOR HEATING THE BOILERS OF LOCOMOTIVES—CANDLE LAMPS—THE WORKING OF BRONZE—VOLATILITY OF CHLORIDE OF GOLD—NEW REMEDIES.

THE facts collected in Paris by Dr. Burg, and in London by Dr. Clapton, which seem to conclusively establish that men who work with copper and its alloys are protected from cholera, have led a M. Adeline to produce a fabric in which fine copper wire is interwoven. He calls it "Anti-cholera tissue," and it is intended, we presume, to be made into belts or underclothing to be worn next the skin. The idea is ingenious, and if an outbreak should occur, there would probably be a great demand for anti-cholera tissue.

The heavy petroleum oils have been successfully applied by M. Deville to the heating of the boilers of locomotives. Two engines on the Strasbourg line have been fitted with M. Deville's furnaces, and are employed in the goods traffic. The consumption of oil in the engines drawing heavy trains is stated to have been from three and a half to five kilogrammes for every kilometre traversed, or (say) from 8lb. to 12lb. for every two-thirds of a mile. This result is considered highly satisfactory by French engineers. The oil is said to be very completely burnt, and there is no waste, and consequently no smoke. Another advantage, which should induce the directors of the Metropolitan Railway to look into the matter, is that, there being no sulphur in the oils, the atmosphere of their tunnels would be free from the most disagreeable and obnoxious contamination, sulphurous acid. We shall endeavour soon to give our readers a full description of these furnaces.

Amongst the things likely soon to find, along with flint implements, their only appropriate place in a museum of antiquities are unquestionably snuffers, instruments, we may say, characteristic of the dark ages. We have nothing to say here about snuffers, concerning which, however, a great deal might be written; we only notice now the lingering affection some people have for candles. If they have a gas light, they wish to have it made as much like a candle as possible. To indulge the whims of such people M. Radowski has produced a petroleum lamp in the form of a candle. The reservoir is of copper, painted white; it contains a sponge to absorb the petroleum, and a wick is carried through a tube, as in the small chamber lamps made on the same principle. The worst of these lamps is, that it is necessary to use a light and consequently dangerous oil in them. If, however, care be taken to pour out all the oil not absorbed by the sponge, and they are filled and trimmed by daylight, no accident is likely to happen. If upset, there is nothing to run out, and there is no possibility of fracture. There is little to be said about the light they give; but they are certainly cheap. The inventor of these candle lamps estimates that the cost of oil for each candle will not exceed half a farthing an hour.

An important fact for the manufacturers of chloride of gold is mentioned by M. Debray, whose word may be safely relied upon in all matters of this kind. It is commonly said, and we believe stated in all chemical books, that when chloride of gold is heated, the chlorine is driven off, and spongy gold left behind. According to M. Debray, however, this is an error. At 300 deg. Centigrade the chloride, he says, is volatilised unchanged. This, M. Dumas remarks, will account for the diffusion of gold in quartz in extremely thin veins.

The secret of the manufacture of Chinese gongs seems to have been revealed recently by MM. Jullien and Champion, who have found that bronze which is brittle at the ordinary temperature becomes malleable at a dull red heat. The makers of bronze implements of anti-historic times were evidently aware of the fact, and no doubt also the manufacturers of the bronze lamps found in the buried Italian cities. Lately they have made experiments on this matter at the Paris Mint with the view of determining the conditions most favourable to working the alloy, and it has been found that a bronze containing 20 per cent. of tin, which at the common temperature is as brittle as glass, may at a dull red heat be forged and beaten out as easily as soft iron. These results open up the way to a new branch of manufacture.

We may dispose in a few words of some matters which at a future day may be of great importance to the comfort and welfare of humanity. Dr. Matthiesen, continuing his researches on opium alkaloids, has found that what has been called papaverine is really a mixture of two alkaloids, one of which is a more powerful sedative than morphia.

The discovery of the anæsthetic properties of chloral has induced people to experiment with its chemical analogues, bromal and iodal. They are disagreeable bodies to use, provoking a running at the nose and a profuse flow of tears, but they are said to be powerful anæsthetics, too powerful perhaps to be safely used. Bromoform, the analogue of chloroform, appears to be more powerful than this latter, and may perhaps be safely employed.

ON THE NEED OF FURTHER EXPERIMENTS ON THE STRENGTH OF MATERIALS.

By Mr. C. J. Light.

AT a meeting of the Society of Engineers, held on Monday, the 15th inst., Mr. F. W. Bryant, President, in the chair, the following paper was read:—All sound engineering practice must necessarily be based upon experimental research into the strength of the materials employed, whether these experiments are purely scientific, and conducted with the accuracy and precision necessary to qualify them for supplying data on which to base formulæ for general use, or of a rough and ready character hardly to be recognised as experiments. For even the most ordinary proportions of parts must originally have been based upon trials—very often upon failures. It is with the former class only that the author now proposes to deal, and to point out how far, in some very important branches, it has hitherto failed in answering its proposed end. Two essentials of useful experiment are, that all action whatever that could interfere with the sole development of the strains to be investigated should be carefully eliminated, and that the apparatus used should possess the means of measuring the results with the utmost possible accuracy and delicacy. These points are essential because, where they are neglected, it becomes difficult to say what are even the limits of error, much less what corrections have to be applied to the results obtained. If this be thought too much of a truism, it will be sufficient to refer to the practice, once almost universal, of applying tensile strains by hydraulic pressure, and measuring the force by means of a gauge connected directly with the press itself, when the friction of the cup leathers introduced an element of uncertainty which entirely vitiated the accuracy of the results. When the object of the experiments is to establish formulæ, it is clearly necessary that, besides the above-named conditions of the apparatus, the samples operated upon should be prepared with the utmost care and precision, but the author would suggest that at the same time samples should be prepared from identically the same materials, but under as nearly as possible the ordinary conditions of manufacture, so that a comparison of the two classes might afford data for determining what proportion of the theoretical strength might reasonably be calculated on in practice.

Of late years great numbers of experiments have no doubt been made, especially upon the resistance of iron to tensile and transverse strains, but they have been generally for private purposes, and have not been allowed to become known. A noteworthy exception, however, is the valuable series of experiments in wrought iron and steel carried out by Mr. Kirkaldy for Messrs. Napier, and so fully published, with their permission. Upon the questions of tensile and transverse strains, therefore, it may be said that our information is fairly complete, but on the highly important subject of compressive strains it is admitted on all hands that reliable data are sadly needed. In a recent communication to the Institution of Civil Engineers, a French authority, M. Gaudard, remarks that "the case of a pillar pressed upon its bases is very imperfectly understood. We are almost reduced to the application of formulæ purely empirical, which aim rather at conforming to observed facts than at explaining them." Whether the formulæ we have to rely upon deserve even the modified description of "conforming to observed facts" may well be doubted after a very slight examination and comparison.

It is surely a matter of great surprise that the best series of experiments into the strength of columns and struts dates as far back as the year 1840, when Mr. Eaton Hodgkinson tested a considerable number of small columns of various diameters and proportions with the express object of determining practical formulæ. Since then nothing further has been done in this direction, and the results at which he arrived are still the admitted basis of calculation for columns and struts. It might, therefore, have been expected that these results were so clear and satisfactory as to render further investigation unnecessary, which, however, is very far from being the case. For example, the well-known formula for long hollow columns with both ends fixed, that is, according to Hodgkinson, columns whose length exceeds thirty diameters, is—

$$W = 44{\cdot}34\,\frac{D^{3\cdot55} - d^{3\cdot55}}{L^{1\cdot7}}$$

Where W = breaking weight in tons.
D = external diameter in inches.
d = internal diameter in inches.
L = length in feet.

On seeing so peculiar an index or exponent as 3·55 in a professedly empirical formula, it is natural for the student to suppose that the experiments rendered results at least very closely approximating to the index finally adopted. What, therefore, must be his surprise to find that in fact the indices obtained from the various experiments ranged from 3·922 to 3·412? (see the foot note to page 333 of Mr. Hodgkinson's work). That is, if the external diameter be 12in., the factor to be employed might range from $12^{3\cdot922} = 17082$, according to one experiment, to $12^{3\cdot412} = 4810$, according to another. The same remark applies to the factor $L^{1\cdot7}$, as it appears that the index varied from 1·914 to 1·424.

In the sixth edition (1867) of Barlow on the Strength of Materials, edited by Mr. Humber, a short article on cast-iron columns has been inserted, which is an almost verbatim extract from Hodgkinson's work above referred to, and in which his formulæ are adopted as the best yet known, with a modification suggested by Mr. Hodgkinson, viz., taking the index of the diameter as 3·6 both for columns with fixed and with rounded ends. It is somewhat anomalous that, while adopting this modification, the effect of which is very considerable even in columns of moderate diameter, what may be almost called the affectation of extreme accuracy is retained in the constants of 44·3 for hollow and 44·16 for solid columns, where it is obvious that the decimal part exercises an influence upon the result perfectly insignificant as compared with that of the slightest change in the indices.

Another serious cause of uncertainty arises from the admittedly different kind of resistance offered by very long and very short columns, the one being principally a resistance to crushing and the other to flexure. Mr. Hodgkinson came to the conclusion that his formula for long columns could be adapted to short columns, at least for certain classes of iron, by means of the following expression:—

$$\text{Breaking weight of short column} = W' = \frac{W \times C}{W + \frac{3}{4} C}$$

where C is the crushing force in lbs. belonging to the material employed × the sectional area of the column. As, however, C will in all ordinary cases be very large in proportion to W, the expression practically resolves itself into $w = \frac{4}{3}$ W.

Now it is obvious that this is a most unsatisfactory solution, for it cannot be supposed that there is any point at which a sudden change of so

considerable an extent takes place. Or, to bring the question to the test of an example, let it be supposed that the column whose breaking strength is sought is 30ft. long, 12in. external, and 12in. internal diameter, is it to be classed as a long or a short column? In the former case, its ultimate strength would be, according to Hodgkinson's formula, 442 tons, in the latter 589. Nor, if it be admitted that there are two such distinct classes as long and short columns, is there any certainty as to the proportion at which the change occurs, other authorities placing it as low as five diameters in the case of cast iron.

Leaving for a time the consideration of Hodgkinson's formula, the next that claims attention is that given by Professor Rankine:—

$$W = S\frac{f}{1 + \frac{l^2}{c r^2}}$$

Where S = sectional area of a column, l = its length in inches, r the least radius of gyration of its cross section, f and c two coefficients depending upon the material, and appearing to have relation to its powers of resistance to compression and tension. It will be seen that no comparison can be made between this formula and Hodgkinson's, but it is evident that Rankine's bears a more purely theoretical character, and that it involves the fourth power of D, in which respect it agrees with that originally laid down by Euler, which Hodgkinson thought could only be reconciled with practical results by modifying the index as before noticed.

Besides these formulæ, there is also one quoted by Molesworth, though from what authority it was derived the author has been unable to ascertain. It is given on the 19th page of his Pocket-book, and called an "Approximate Rule for the Strength of Iron Struts," without any limitation as to the proportions between their length and diameter. For the case of hollow columns of cast iron this rule gives—

$$W = S \times 36 \div 1 + \frac{l^2}{400\ D^2}$$

$$\text{or} = S\ \frac{36}{1 + \frac{l^2}{400\ D^2}}$$

Rankine's formula adapted to a similar case would be

$$W = S\frac{80{,}000}{1 + \frac{8\ l^2}{3{,}200\ D^2}} \qquad = S\ \frac{80{,}000}{1 + \frac{l^2}{400\ D^2}}$$

so that the forms are identical, while the difference of the coefficient is, in this case, but trifling, as Rankine's formula gives the value of W in lbs., and 80,000lb. = 35·715 tons. When, however, the material of the column is wrought iron, the similarity of form continues, but the coefficients differ so greatly as to cause great discrepancy between the results, a discrepancy varying with the relations between the length and diameter. The same remarks apply to the formulæ given for columns of a hollow square and a cruciform section. To assimilate the formulæ for wrought iron to those of Rankine, they must be altered thus:—

For cruciform section, $16 \div 1 + \frac{l^2}{1500\ D^2}$

For hollow square section, $16 \div 1 + \frac{l^2}{3000\ D^2}$

For hollow cylinder section, $16 \div 1 + \frac{l^2}{4500\ D^2}$

In order to show how great is the variance between the different formulæ, and therefore how uncertain any calculations of the strength of columns must be, it will now be desirable to give the results in a few practical instances. First, let the case be that of a cast-iron column 30ft. long, 12in. external and 10in. internal diameter, with the ends flat. Hodgkinson's formula will give its breaking weight, if it be considered as a long column—

With index 3·55 . . . . . 442 Tons
With index 3·6 (said to be sufficiently near for practice) . . . . 505 „
If taken as *short* column . . . 589 „
Or the same with index 3·6 . 631 „
According to Rankine's formula, taken as long column . . . 380 Tons
According to the formula on page 19 of Molesworth . . . . . 383 „

Which of these results, the extremes being as 5 to 3 very nearly, is to be taken as the true breaking weight of the column?

Again, take the case of a column, also of cast iron, 30ft. long, 24in. external and 20in. internal diameter, with the ends rounded, or, what is the same in effect, jointed. Hodgkinson's formula gives, with what he considers the true index for D, viz., 8·76—

Breaking weight . . . . 3,080 Tons
With the index 3·6 ("quite near enough for practice," let it be remembered!) . . . . 1,797 „
Or, if it be taken as a *short* column, which at the proportion of 15 diameters to the length, we have a right to do . . . . 4,107 „
Taken as a long column, by Rankine's formula . . . . . . 1,519 ,
By formula page 19 Molesworth . 955 „

In this case, the extreme values obtained for W are to one another as 43 to 10, very nearly. How is it possible to arrive at any idea of the real strength of such column, which is yet one of very probable dimensions. If, however, wrought iron be the material employed, the discrepancies become still more startling. Assuming the case of a similar column to the one first instanced, only in wrought iron—

Hodgkinson would give . . . 771 Tons
Rankine . . . . 463 „
Molesworth . . . . . 170 „

The first result is based on the statement that the relative strengths in long columns of wrought and cast-iron are as 1745 to 1000—an hypothesis which must be entirely erroneous, for the ultimate crushing strength due to the area of this column, without any consideration of its liability to flexure, is only 586 tons (calculating at 88,000lbs. on the square inch).

The uncertain results of Mr. Hodgkinson's experiments must, there is no doubt, be chiefly attributed to the small size of the columns operated upon, and not to any want of skill or care on the part of the operator. The largest solid column tested was only 5ft. long and 2in. diameter, and in hollow columns the greatest length did not exceed 7ft. 6in. with a diameter of 3¼in. The more powerful means of testing now at the command of engineers would allow of experiments being made upon a much larger scale, and, it is reasonable to anticipate, with far more uniform results.

Before leaving this part of the subject it will be well to notice a remark of Mr. Hodgkinson ("Phil. Trans." 1840) respecting cases of imperfect casting in hollow columns, where the metal on one side was considerably thinner than on the other. He says, "It is gratifying to find that a matter which would seem to destroy all confidence in a pillar does not produce a great reduction in the strength." This apparent anomaly he explains by supposing that by some natural law the thinner side always takes up the compressive strain, and the thicker the tensile, and the instances that accidentally occurred among his experiments certainly confirmed this supposition. This will be an important point for future observation.

In reference to wooden pillars or columns, it will be sufficient to remark that the best established formulæ give results which differ from each other in a similar manner to those for iron, though not to quite the same degree.

Enough has probably now been said to show how impossible it is, with our present information, to determine within anything but the roughest approximation what load any given column ought to bear before breaking. It is true that even if strict accuracy were attainable in this respect, there would yet remain the variations of material and workmanship to be allowed for, besides the important question of the factor of safety that should be adopted. But the author would urge that we ought not to be content until a theoretical basis has been established as certain and rational as that upon which calculations of transverse strains are now based.

Another class of experiments, much more readily to be made, and of a much simpler character, would yet be of great practical utility. Their object would be to determine the resistance to transverse and compressive strains of wrought-iron L and T bars of various sections, and to deduce therefrom practical rules. It is very probable that ample materials already exist in private hands for compiling such information, and, if not, the necessary experiments could be easily and cheaply made. This is not a case requiring extreme accuracy, especially as it would be the actual full-sized bars that would be operated upon, but every engineer ought to have the means of determining at a glance what load any given bar will properly bear. Such tables would be the means of saving many a ton of metal in roofs and flooring, &c., and would afford the designer an assurance of the efficiency of his structure, which he cannot at present be said to have.

The next series of experiments to the need of which the author desires to call the attention of the society would require very great care and skill, both in arranging and in carrying out. They refer to the true proportioning of the eyes of links. It is now many years since attention was first directed to the necessity for providing, not only a sufficient shearing area in the bolts or pins securing links, tie rods, &c., but also a sufficient bearing area of the link or tie itself upon the bolt, a point which appears to have been overlooked, at least in civil engineering, until the rapidly extending use of iron roofs, and the desire to reduce every part to the lightest possible form, brought it into prominence. And even now there is great difference of opinion as to the extent of such bearing area, some authorities contending that the crushing strain so induced ought not to be allowed to exceed (for wrought iron) 5 tons to an inch, while others would extend the limit to 7 or 8 tons. The correct proportions for the eyes of links, whose thickness is small in proportion to their breadth, as in those of bridges, still present a vexed question; and it is not easy to determine how far they are affected by the unavoidable irregularities of manufacture.

Experiments appear to show that the proportions at present adopted in the best practice, though greatly modified from those at first used, are even yet insufficient to secure the fracture of the link through the body in preference to the eye. The author submits that it would be highly desirable to arrange and carry out a series of experiments on links of graduated cross sections, from the thin link, as employed in the lower members of bridge girders, to one of a square section, with a view to determine the proper proportions for the eyes under these varying conditions. It is, however, quite probable that a large amount of information already exists suitable for such a determination if it could only be brought together under such conditions as to permit of a fair comparison of results.

Upon the strength of timber as a material of construction there have been made so great a number of experiments that it may be doubted whether fresh ones would add much to our knowledge of the subject. It may be remarked, however, that the greater part of these, also, are open to the objection before referred to of having been made upon exceedingly small pieces. It is also true that with timber so very much depends upon the age, the growth and the place of growth of the tree, that it can never be expected that calculations for this material can be brought within the same limits of accuracy which may be fairly looked for in the case of iron.

Further experiments are probably desirable on the strength of combinations of timber and iron, such as trussed beams, keeping in view the consideration that the timber must necessarily yield to a considerable extent before any appreciable strain is brought upon the iron tie. This objection is of much greater force in the case of the flitch girder, in which the timber ought only to be looked upon as giving lateral stiffness to the iron plate.

In reference to the important question of the strengths of stone, brick, cement, and artificial stone, there is still room for a well-arranged series of experiments, especially if made upon much larger samples than those which have hitherto been operated upon. Another interesting subject for fuller experiment is that of glass, as laid in sashes both of wood and iron. In the latter case observations should be made under varying temperatures. Several other branches of the inquiry will doubtless be suggested in the course of discussion, and the object of this paper has been, not so much to call the attention of engineers to a want which the author is well aware is already known and admitted as to elicit from all who take an interest in the subject such information as they can contribute to the common fund and such suggestions as may lead to a practicable remedy for a state of things which cannot be considered creditable to the present position of engineering science.

If the foregoing fairly represents the present state of our information upon this important subject, it remains to consider what means can be suggested for satisfactorily supplying the defi-

ciency, and obtaining data upon which reliable formulæ might be based. The best course would probably be for an adequate series of experiments to be carried out covering the whole field of inquiry on any one branch of the subject—say that of columns and struts—to be conducted under the direct superintendence of two or more engineers of such standing as would give weight and authority to the results at which they might arrive. But this course would necessarily involve a very heavy expense, such as no individuals, and probably no body of engineers even, would be inclined to bear. The author would therefore suggest that the same desirable result may be attained by organizing a system of co-operation, whereby the expense may be so spread as not to be felt a burden. To this end three things appear to be essentially necessary. First, that all the experiments should be conducted according to a pre-arranged form, and by means of one and the same testing machine. Secondly, that with each experiment on strains of compression a piece of a standard size from the same melting as the castings to be experimented on should be subjected to the test of crushing, so as to furnish a datum of comparison with other cases, and similarly of course with other materials and other classes of tests. Thirdly, that there should be a central body or committee to which all information should be sent, and by which it should be analysed and sifted, all that might be thoroughly reliable classified and tabulated, and finally its results carefully formulated.

The author would suggest that the Society of Engineers might well take the initiative, and appoint, through its Council, a small committee to act as such a centre; that any member of the society holding the position of engineer to works of sufficient magnitude should use his influence to have a small sum set aside, either by the principals or the contractors, for the purpose of experiment, the special object of which should be arranged with the central committee; and that the co-operation of engineers not connected with the Society should be invited for the same object. The objections anticipated are, that where testing is resorted to in connection with public or private works of construction it is generally for the private purposes of the parties concerned, and that there might probably be great disinclination to allow the materials used to be experimented on if the results were to be made public. Again, it may be feared that the engineers most qualified to form the proposed central committee would not be able, assuming that they would be willing, to devote the necessary time to the work of arranging and formulating the information sent to them.

The author would meet these difficulties by the consideration that if the first-named condition, ensuring uniformity in the mode of conducting the experiments, be secured, the time over which the inquiry might be spread would become of less moment. At the same time he is sanguine enough to believe that if the object be found to be really important there are plenty of qualified men who would be ready to give a portion of their intervals of leisure for the furtherance of an inquiry which should give a complete and satisfactory answer to questions of daily importance to our profession and to all connected with the arts of construction.

CONTINUOUS RAILWAY BRAKE.

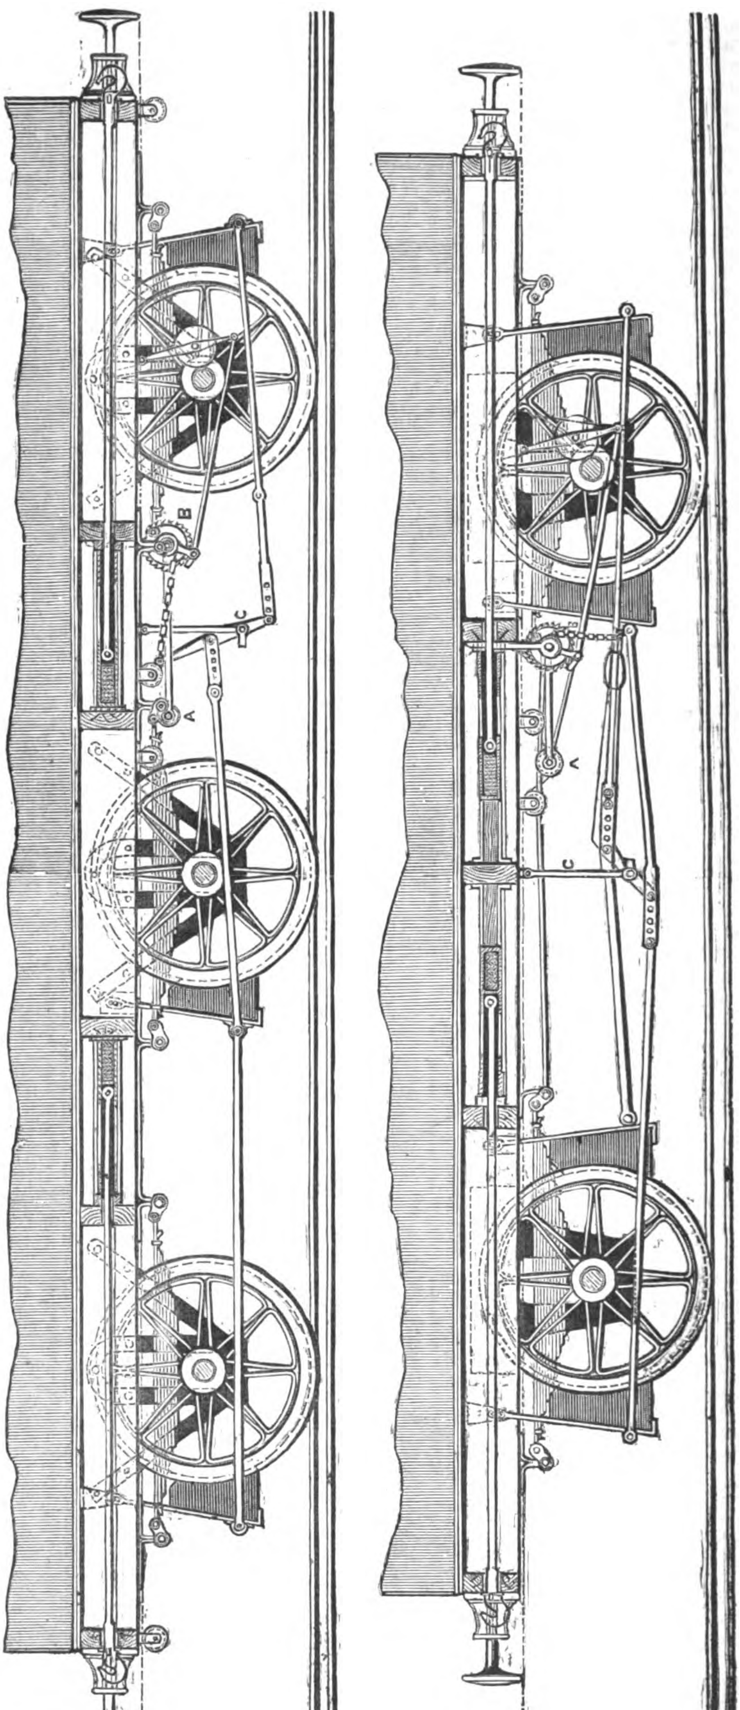
In the annexed engraving we have represented a very efficient self-acting railway brake, as applied to carriages on the Midland Railway, and the invention of which is due to Messrs. Wilkin and Clark, 10, South-street, Finsbury. This brake was first introduced into practice on the Metropolitan Railway some two and a half years since, by Mr. Burnett, the locomotive superintendent of that line. Subsequently to that time, and when the brake had proved to be a practical success, the officials of the Midland Railway saw the invention, and forthwith introduced it on thier line. The difference between the application of the principle on the Metropolitan and on the Midland lines is, that on the latter the brake is self-acting, whilst on the former it is not. The fundamental principle, however, remains the same, the difference being that on the Midland Railway the line is slackened when the brake is applied, whereas on the Metropolitan it is wound up.

In this apparatus, as adopted on the Midland line, we have first a small (3-16in.) chain, which is carried on sheaves fixed to the carriage framing. It is placed in the centre line of the train, so that the carriages may be turned end to end without affecting its operation. The chain is simply hooked together on making up the train. The chain is carried under a pulley in a weighted operating lever A, and while the train is running the chain is kept taut by a counterbalance weight in the van, and keeps the several levers suspended. When the guard wishes to apply the brake he turns a small hand drum and overcomes the frictional resistance of the chain (for both weights act as a counterpoise), and the chain is slackened throughout the train. On the framing a spindle 2¼in. in diameter, carrying a ratchet wheel B, is fixed. The ratchet wheel is not fast upon the spindle, but is carried in frictional clutches. When the operating lever, which is loaded to 35lb. weight, is dropped, these clutches bind the ratchet wheel; motion is given to the ratchet wheel by the revolutions of an eccentric wheel running upon the revolving axle. Attached to the spindle is a ½in. chain, which being wound up operates the levers and blocks in the usual way. The brake levers are carried by a sling C to equalise the pressure of all the blocks. The wheels are, as a rule, not skidded, but nearly so, which is the best result both for practice and tear and wear of stock. When the brake is out of gear the eccentric wheel is held clear of the axle, so that there is nothing in operation till the brake is wanted.

It will be seen that the principle of this brake differs from others in so far as the guard has to keep it from working till he requires the brake, when he slackens the operating chain, and the

CONTINUOUS BRAKE—MIDLAND RAILWAY.

BY MESSRS. WILKIN AND CLARK.



brake is then allowed to act of itself. One important point of this positive or self-acting arrangement is that so long as the train is coupled together, and the guard with it, he can keep it out of gear. But if by accident the train breaks away on an incline he has no longer power to keep the traffic off, and it then becomes self-applied, without any direct human agency whatever. This point was very efficiently tested by the Midland Railway before the train to which the brake is fitted was put on passenger service. The driver was ordered to run down a gradient of 1 in 90, and after attaining a speed of thirty miles per hour the train was parted from the engine precisely as if by accident, and the train came to rest on the bank in 200 yards, or fifteen seconds of time. A similar experiment, but at fifty-five miles per hour, was next tried. Another train stopped in 330 yards, or twenty-seven seconds. As a further test of its power, the driver was ordered to get up full speed and keep on full steam; the brake was then applied, and, without shutting off steam, the train was stopped in 1,220 yards. The engine was a four-wheeled coupled engine, with 16in. cylinder, working up to 140lb. The train has since been working regularly for the last ten weeks on the Midland Railway, and is giving very favourable results. The action of the brake is so uniform and steady that it is not possible to tell when it begins to bite. At a speed of forty miles per hour the train was stopped in 25 seconds, or 280 yards in regular work. The lower figure in our engraving shows a modification of this brake, the principle, however, remaining the same. We understand that the system is now being fitted to the whole of the Metropolitan Railway rolling stock.

THE SOCIETY OF ARTS.

On Wednesday the 116th session of the above society was inaugurated by an opening address from Lord Henry G. Lennox, M.P., Chairman of the Council. After a reference to matters pertaining to the conduct of the society's affairs, the Chairman alluded to the committees appointed by the council to examine great practical questions, foremost amongst which was the Food Committee, which had given its attention to the supply of meat, fish, poultry, milk, and grain, together with their distribution. The great problem at present was the means by which meat could be brought to this country from our colonies and other countries in a raw state, unsalted and uncured. The committee had examined many processes for this purpose, and had put them to the test, and only a few days ago Lord Granville had forwarded some packages of preserved meat from the colonies in order that the Food Committee might ascertain whether the meat was in a fit state to be supplied to our soldiers and sailors. At present the plan which held out most prospect of success was that which presented the least novelty of conception—namely, the preservation of meat by means of ice, and the practical conclusion to which the committee were brought appeared to be that as yet an increased supply of meat to the people of this country depended upon the success of scientific chemists in producing artificial ice at an economical rate.

The council intended this session to appoint a Mechanical Committee, composed of professional men and amateurs, who would discuss subjects relating to progress in mechanical inventions, and who may, it is hoped, be enabled to turn their attention to the subject of the best steam or other roller for macadamised roads. Intimately connected with mechanical inventions was the Patent Law, upon which Sir Joseph Whitworth had promised to read a paper, and which was about to be discussed in the French Legislative Chamber. As an instance of the difficulty thrown upon the judges at present in deciding what is and what is not new, the Chairman said he was informed that on a recent occasion the Master of the Rolls, being otherwise unable to decide between two opposing litigants, ordered the erection in the yard adjoining his court of two elaborate models of the machines which formed the subject of dispute.

The Chairman observed that art-workmanship was still encouraged by the society, which offered for the present session a large number of prizes for productions in most branches of art workmanship, additional prizes being offered for specimens of the application to industry of prescribed art-processes. Passing to the subject of cheap postage, the Chairman stated that it would be the duty of the council to collect information bearing on the expediency of allowing printed matter and parcels to be conveyed through the post at a cheap rate. The council had good reason to believe that the attempt in Switzerland to combine a cheap parcel post with a cheap letter post and cheap telegraphy had been successful, and that in Switzerland and some parts of Germany the substitution of a half-penny rate for the transmission of printed matter as well as newspapers had produced receipts equal to the old penny rates which they had replaced. With regard to the acquisition of telegraphs by the Government, it would be the duty of the society to watch scientific improvements, to see that they had a fair trial, and if possible to promote cheapness in the transmission of messages. The Channel passage was the next subject passed under review. The Society of Arts had offered a premium for improving the communication between France and England, and 17 models of boats had been sent in, which would be examined by a special committee. The Chairman's opinion was that a line of powerful steamers like the new Holyhead and Dublin boats, and doing the passage in about an hour, would meet every reasonable want, and the Dover Pier, which had cost £750,000, could easily be made available for such boats if the French Government would construct a corresponding pier at Calais or Boulogne. One of the schemes for making a tunnel under the sea would be unfolded before the society in about a fortnight. Then came the schemes for a bridge across the Channel, especially that of M. Boutet, which was reported to be favourably looked upon by the Emperor Napoleon, and which was well deserving of the notice of our engineers. In concluding his address, the Chairman reminded members that the library had been re-arranged, and a reading and news-room attached to it, with every convenience for members coming up from the country who wished to conduct their correspondence there.

After the address, Mr. W. J. Wilson was called up to receive from the Chairman the Prince Consort's prize of 25 guineas.

APPARATUS FOR WEDGING FACING-POINTS.

After the meeting of the Institution of Civil Engineers on the 9th inst., Mr. Harrison (V.P. Inst. C.E.) explained a model and two drawings, illustrating plans which had been successfully tried on the North-Eastern Railway, with a view to provide the means of preventing accidents at facing-points. These accidents had arisen from various causes. In some well-established cases, a blow from a waggon or carriage on the heel of the switch rail had sprung the point sufficiently to throw a carriage off the line. A piece of coke or stone getting behind the points, which would stop them from entirely closing, might not prevent the lever worked by the signalman from apparently coming home, without any defect being detected, owing to a certain amount of elasticity in the lever. Signalmen were frequently in the habit of putting up the danger signal before a train had quite passed, and, with the jerk, sometimes disturbing the facing-points. When the Queen's train passed over the North-Eastern Railway, it was the invariable practice to wedge up all the facing-points on the line; and it was believed a similar plan was adopt d on the Brighton and South-Eastern Railways before express trains passed. This had led him to the adoption of the present plan. The first idea was to employ a separate lever to work the wedges distinct from the points. This had been in use at the Pensher Junction for some months. It was afterwards thought that the turning of the points and the wedging might be done by one motion of the lever. This was accomplished by giving a double action to the wedges; but the segment movement, as shown by the model, was in practice the best, and had been in use for some time at Gateshead, on the Team Valley Line. Experiments had been made by putting an obstacle between the points and the rail; but in this case the wedges could not be forced home, the danger-signal could not be lowered, and intimation was at once given that something was wrong. The slide motion for moving the points was worthy of attention, independent of the wedges, as no slight or even considerable motion of the lever could move the points, and practically this motion in itself wedged them up. The cost was rather under £15 per junction, and the same handle was used which before worked the points.

In carrying out these arrangements, Mr. Harrison stated that he had been assisted in all the practical details by Mr. Simpkin, who had the charge of this department on the North-Eastern Railway; and he was so satisfied with the additional safety to be obtained by this plan that it was to be at once adopted at all facing-points on the main line of the North-Eastern system, and in some cases facing-points would be introduced where heretofore all trains had been back-shunted to avoid them. In all cases this arrangement was used in conjunction with a locking apparatus for the signals, &c.

Mr. R. Price Williams (M. Inst. C.E.) also exhibited and explained a new arrangement of switches for railway junctions. The main object of these switches was to do away with facing-points and their attendant evils, and to enable a train when passing through a junction to pass over a continuous and fished main line, or a continuous and fished line leading to the branch, according as circumstances might require. The switches were formed of lengths of rails, of the same section as the rails used at other parts of the road, with fishes at both extremities, at one end the bed-plate admitting a slight play, while at the other they were capable of being moved laterally on the removal of the fish-plates. Each length of what might be termed the main line switch rail was firmly attached to the corresponding length of branch line switch rail, so that the two mutually supported each other, thus giving the necessary lateral stability. At the ends of the switch rails, capable of being moved laterally, sliding double fishes were employed. These moved on the fixed rails, and were so formed that when moved forward they held the switch rails firmly between their jaws, and thus ensured that the switch and the fixed rails were maintained fairly in line with each other.

TRIALS OF H.M.S. "ROCKET."

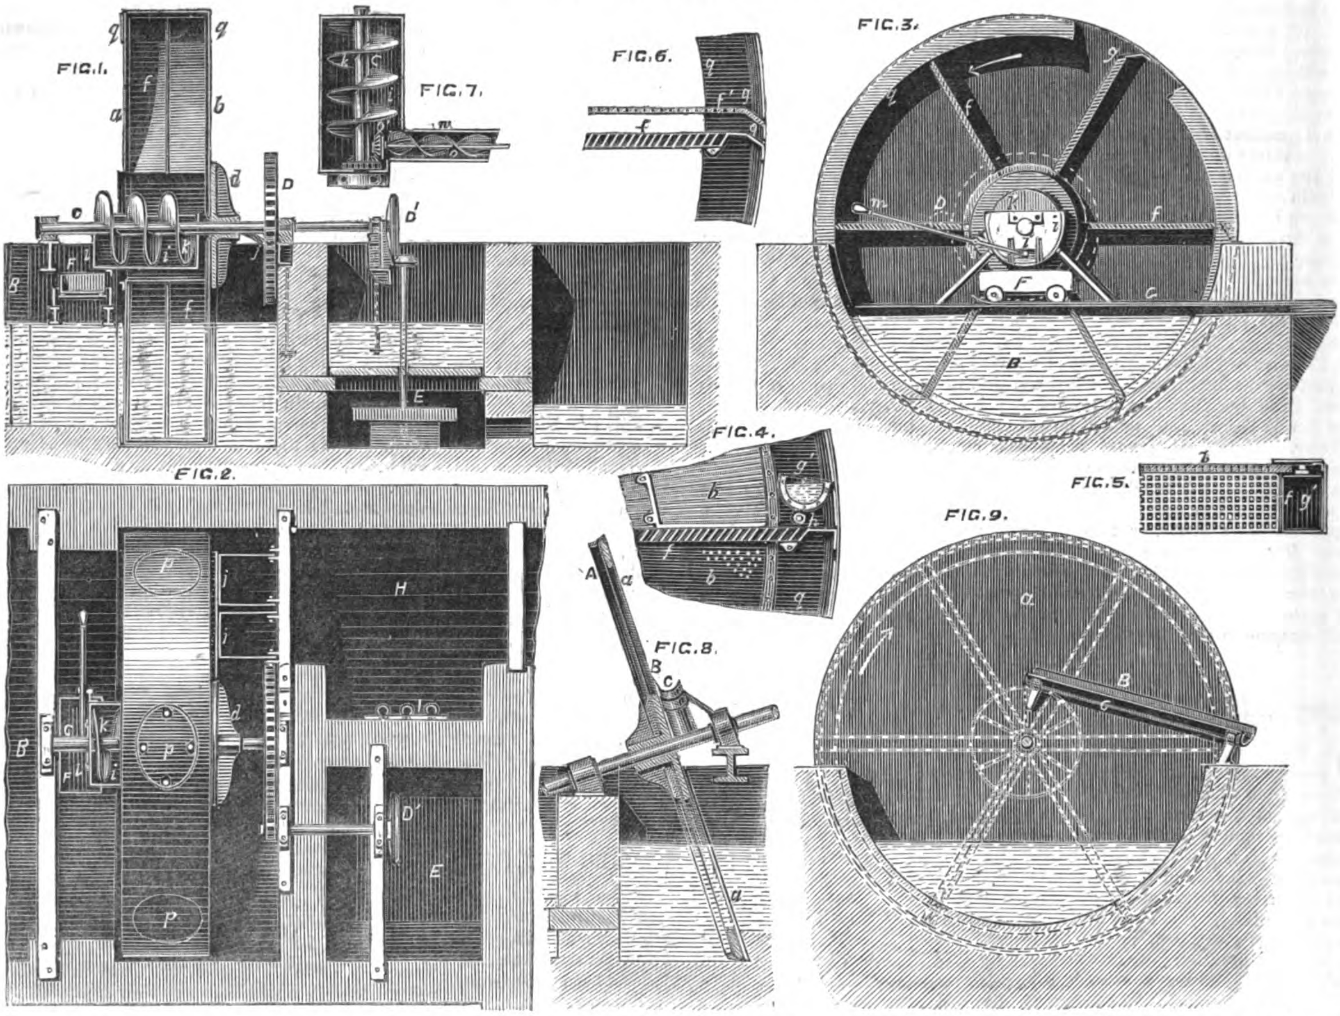
On the morning of this day week the gun vessel "Rocket" was taken out for the second time to the measured mile at the Maplin Sands, to try her boilers and machinery, the first trial having been very unsatisfactory. Upon this occasion the "Rocket," which is sister ship to the "Thistle," being of the same dimensions, steam power, and tonnage, and carrying the same number of guns, had an exceedingly narrow escape from an explosion. The trials were conducted by the officers of the Steam Reserve, and while the vessel was going at full speed on the mile the boilers primed to such an extent as to blow nearly all the water out of them, rendering it necessary to draw the whole of the fires. The alarm on board, especially in the engine-room and stokehole, was, as may be supposed, very great, being naturally heightened by the remembrance of the calamity on board the sister vessel. Some of the men became so unnerved as to be obliged to go on deck; but others manfully remained at their duty, and by their exertions prevented another catastrophe. Various rumours are current as to the cause of the priming, but nothing positive has been made known. The fires were subsequently got up again, and the ship completed some of her trials.

PASSAGE OF THE MISSISSIPPI.

Grave complaints are again made of the shallowness of the water on the bar at Southwest Pass, the mouth of the Mississippi. On October 24 there were nearly twenty large vessels lying outside the bar, waiting to be lightened. Nearly all of them were from foreign ports, and all had heavy cargoes of goods sadly needed in New Orleans and the Southern States, while the inability of vessels to get in interfered with the export of cotton. The "New Orleans Picayune" is anxious to have some good system adopted for lightening vessels over the bar, and is sure it will prove detrimental to the commerce of New Orleans when ships drawing over 17ft. water are compelled to lie out in the gulf until some unusually high tide will carry them over the bar. The New Orleans press generally despair of any permanent relief being obtained. There have been many projects and experiments about deepening the water, but nothing substantial has been realised, and the suggestion is now made that the Government dredge boat be used in towing vessels through the mud, since her ability to clear it away has proved a failure. The volume of water on the bars varies considerably, there being a greater depth of water when the river is from 12ft. to 15ft. below high-water mark than when it is at a high stage. In the former case the tides flow further in, and on their return carry out large quantities of deposit, while in the latter the bulk of the river water breaks the force of the tide from the gulf on the bars and causes a large deposit. No dredging system is able to remedy the evil.

APPARATUS FOR FILTERING AND STRAINING SEWAGE.

BY MR. BALDWIN LATHAM.



APPARATUS FOR FILTERING AND STRAINING SEWAGE.

At the conversazione of the Institution of Civil Engineers in May last, we met with a model of a machine for extracting the solid matter from sewage, the invention of Mr. Baldwin Latham, of 6, Westminster Chambers, and Croydon. This apparatus was then being constructed for use at Croydon, and was briefly described by us at the time. We now purpose to describe this invention in detail, as it is of great importance in connection with sanitary engineering. The invention—which has been patented by Mr. Latham—consists in causing the sewage to be filtered to pass through a combination of screening surfaces arranged at right angles to the flow of the fluid, whereby the sewage as it passes through deposits its solid matter upon the screening surfaces, which in travelling along carry the matter away to a point where it is removed from the surfaces, and these then again pass into the stream of sewage to intercept fresh matter. The apparatus adopted by Mr. Latham in practice is illustrated in the accompanying engraving, where fig. 1 is a sectional side elevation, fig. 2 a plan, and fig. 3 a front elevation. A is a drum, the circumference of which is of sheet metal, and which is open at the front face *a*, which is presented to the stream of sewage flowing in the direction of the arrow through the culvert B. The back face of the wheel is closed by a screen *b* formed of perforated plate. If requisite a second screen *c* formed of gratings with larger apertures than *b* is fixed in the middle of the wheel to intercept the coarser portion of the solid matter. The wheel is carried by the shaft C, to which it is secured by the strong cast-iron boss *d* and ribs *e*, and it receives a slow rotary motion in the direction of the arrow by means of gearing D D¹ from a turbine at E driven by the head of sewage water flowing through the apparatus. Inside the wheel A are fixed a number of radial screens *f f f*, formed as a step grating, as shown at the enlarged detail section and part plan at figs. 4 and 5, the inclined transverse bars being intersected by longitudinal bars so as to form apertures of a small size. In place of step gratings, perforated plates or even solid plates may be employed, or an arrangement may be advantageously used, as shown at fig. 6, where a screen *f*¹ of perforated plates is fixed immediately above the step grating *f*.

This construction of step gratings is also applicable irrespective of its combination with the screening wheel for separating solid from liquid matter. Thus they may be fixed in an inclined position and the liquid in which the solid matter is held in suspension be made to flow down them. At the outer ends of the screens are formed either fixed troughs *g*, as at figs. 3 and 6, or a tumbling trough *g*¹, as at figs. 4 and 5, turning on pins *h*, which troughs take up fluid as the wheel revolves, and when the screens have been raised to a certain angle the fluid flows out of the troughs and down the screens, flushing the solid sewage deposited thereon into the central trough *i*. At the same time the solid matter deposited upon the vertical screen *b* (as also on the intermediate screen *c*, when this is employed) by the passage through it of the sewage water also passes down on to the screens *f*. To facilitate this brushes *j* carried by hinged arms may be kept in contact with the outer surface of the screen *b*, or jets of water are directed against the screen for this purpose; but in practice it is found that the rushing back of the sewage water through the apertures of the screen on the descending side of the wheel as it dips into the fluid is generally sufficient to flush the deposited matter off the vertical screen so as to be taken up by the radial screens.

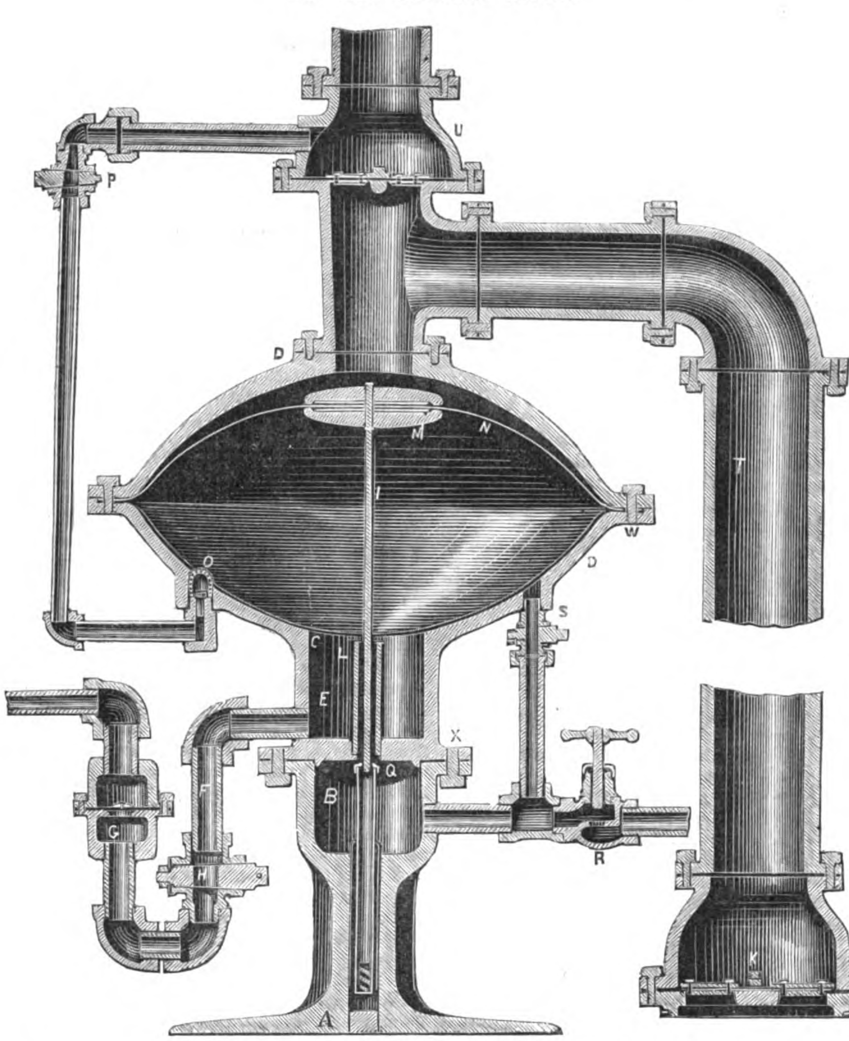
As the separated solid sewage passes into the central trough *i* it is carried forward in it by the revolving screw blade *k* fixed on the shaft C, so as to fall either into trucks F run upon rails G underneath the trough, the front end of which is provided with a sliding door *l* for this purpose actuated by a handle *m*. Or the trough *i* may be made to deliver continuously into a second trough, as shown at *n* in part plan at fig. 7, in which it may be carried forward either by another revolving screw blade *o*, driven by gearing *o*¹ from the shaft C, or by chain buckets. In order to gain access to the radial screens for cleansing them when required, man-holes *p* provided with covers are formed in the circumference of the wheel. Both faces of the wheel are provided with shroudings *q* for the purpose of catching and retaining sand passing in with the sewage, and to strengthen the wheel, and which also serve to close the ends of the troughs *f*. The sewage water, after flowing through the screening apparatus, passes through the channel H and sluice I to the turbine chamber E, whence it flows down the aperture K to the low-level culvert L.

Should it be required still further to strain the sewage after passing through the apparatus already described, it may be caused to flow through a second wheel or disc covered with canvas, which may be arranged as indicated in transverse section and front elevation at figs. 8 and 9, where A is an inclined revolving wheel covered at *a* with canvas, through which the sewage is made to flow in the direction of the arrow, and upon which the solid matter yet contained therein is consequently deposited. As the straining surface revolves it carries the deposited matter round to the fixed scraper B in contact with the straining surface, which removes the deposited matter and causes it to pass into the trough C, in which it is conducted wherever required.

This apparatus is intended to be used in the preparation of sewage before its application by irrigation to land. Hitherto the solid matter of sewage has been removed by tanks, but these tanks have been the only blot upon the system of sewage irrigation. The machine occupies a very limited extent compared with the area required for tanks, the motive power for driving being the sewage itself. The whole of the solid matter is removed in a fresh state before decomposition takes place, and, therefore, this solid matter is much more valuable as a manure than the solid matter taken from tanks, which can only be removed after decomposition has set in. The liquid not having to flow

AUTOMATIC PUMPING ENGINE.

BY MR. THOMAS SHAW.



through a mass of decomposing fœces is much sweeter, and there is no likelihood of the sewage so treated producing a nuisance when spread over the fields of an irrigation area. The apparatus is inexpensive in its cost, and as it performs all the work that has hitherto been performed by manual labour, the great expense of this labour will be saved.

The apparatus is found to be most effective in practice, and we understand that Mr. Latham is putting up a large number. It is very perfect in its working, and will remove from the sewage not only the whole of the solid fœcal matter, paper, rags, sticks, stones, &c., but the fine sand brought down the bed of the sewer, and which often proves a serious source of mischief. It can be applied in any position, as it will work quite as efficiently at any depth below the surface as upon the surface.

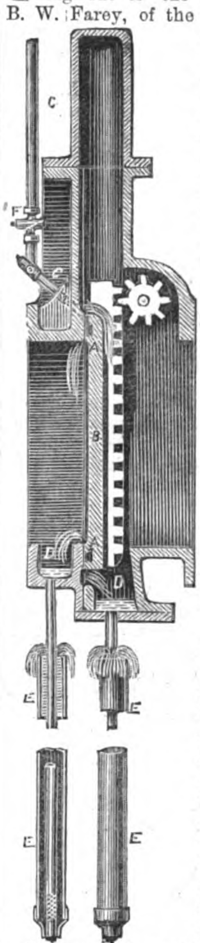
AUTOMATIC PUMPING ENGINE.

THE accompanying engraving illustrates a pumping engine which has recently been invented and introduced in America by Mr. Thomas Shaw, of Philadelphia, whose gunpowder pile driver we described and illustrated in the MECHANICS' MAGAZINE for the 1st of October last. The present machine consists mainly of a spheroidal chamber of cast iron, composed of two equal globular segments united by flanged edges forming a perfect joint, and grasping also the circumference of a circular diaphragm or curtain of stout cotton cloth of several folds, the cloth and the inner wall of the chamber being coated with vulcanite as a non-conductor of heat. This diaphragm has a sufficient diameter to follow the curve of the chamber throughout, and is made to alternate from top to bottom of the same by means of a finely finished steel valve stem, clasping it exactly in the centre by a metal disc on each side. The stem also opens and closes the tubular valve by which the steam enters the chamber from the steam chest. In our engraving, A is the base; D the chamber; N the diaphragm; M the clasps of the diaphragm; E the well for condensed steam; F the escape pipe for condensed steam; I the valve stem; J the tubular valve; Q the valve seat; V the steam pipe leading from the boiler; S the steam entrance for starting; T the inlet water pipe; K valve for same; U the outlet water pipe; and P the cold water pipe for the injector nozzle at O.

The special points of the invention are its simplicity of parts and direct application of power. Watt's great achievement (in the steam-engine) gained its first celebrity as a pumping agent; but Mr. Shaw's machine is a pump which dispenses with the principal contrivance of his truly illustrious predecessor. The communication is nearly direct between the boiler and the pump, the spheroidal cavity serving virtually as steam cylinder, condenser, and pump chamber; and the reciprocating movement almost indispensable to the pumping process is accomplished without any traversing of air-tight surfaces, except by the fine central rod already named, and none of its parts come in contact with the open air. Mr. Hector Orr, of Philadelphia, who has favoured us with these particulars, informs us that this pump has worked without a fault for weeks together without any personal attendance save that necessary for opening and closing the steam cocks. Its stroke is meant to be slow (from five to ten per minute); but the form of the chamber admits of great capacity. The column of water is lifted by the simple thrust of the steam, and the chamber is filled with water by atmospheric pressure attracted by the condensation of the same steam at the right moment. The diaphragm being an elastic partition vibrating between balancing pressures, its comparatively frail nature is fully equal to its office, and after several months' wear (it has worn *ten* months under the eye of the inventor) it can be replaced at a trifling cost. These characteristics entitle the apparatus to the attention of all requiring such machines in England, and who will shortly have the opportunity of judging of the merits of the invention for themselves.

FAREY'S GAS VALVE.

THE gas valve represented in the accompanying cut is the patented invention of Mr. B. W. Farey, of the firm of Messrs. B. Donkin and Co., of Bermondsey. The object is the prevention of any escape of gas between the seatings or faces of the valve. To this end a groove is formed in one or both of the seatings or faces of the valve, into which groove is introduced water or oil, at a pressure exceeding that of the gas for which the valve is employed to regulate or stop the flow. Should the seatings or faces of the valve not be tight a leakage of the fluid will take place, thus effectually preventing all escape of gas between the seatings or faces. Any fluid so leaking through can be taken off by syphons, one on each side of the diaphragm or slide of the valve. When gas valves are used to divide pure from impure gas, pure gas at a greater or lesser pressure than that of the gas in the pipes may be used as a lute instead of a liquid, when at a greater pressure being supplied from a gasometer, when at a lesser pressure the pure and impure gas from the pipes leaking into a gasometer, the object in keeping valves perfectly tight in this case being to prevent any flow whatever of impure into pure gas. While the valve is open the flow of water, oil, or gas into the groove is stopped by self-acting means within the valve.



Our engraving represents an adaptation of this invention to one of Messrs. B. Donkin and Co.'s gas valves. A groove A is formed in the slide B of the valve, into which the fluid is introduced by means of the pipe C at a pressure exceeding that of the gas. Any leakage flows into the recesses D D, one on either side of the diaphragm of the valve, whence it is taken off by means of the syphons E E. The cock F is of course closed when the valve is open, open when the valve is closed.

ON THE MECHANICAL FIRING OF STEAM BOILERS.*

BY MR. JOHN DAGLISH.

THE first part of this paper contains the result of a series of experiments that were arranged and carried out by the writer at Rainton Colliery, chiefly for the practical determination of the question of the utility and economy of side water boxes in connection with Juckes' furnaces, and incidentally to ascertain the advantage derived by covering boilers, and the best materials for that purpose. A second series of experiments are then given that were conducted at Seaham Colliery for the purpose of practically ascertaining with certainty the advantages obtained by the use of mechanical apparatus as compared with firing by hand, and the comparative advantage of various systems of mechanical apparatus. Incidentally, attention was drawn to other points, and experiments were made to ascertain the best rate of motion for the bars, thickness of fire, and distance of boiler from fire-grate. A third series of experiments is then given that were conducted at Silksworth Colliery for the purpose of determining the relative advantage of the Cornish boiler for colliery purposes as compared with the plain cylindrical boiler, prior to erecting a large number for the extensive new coal-winning which is now proceeding at Silksworth. Incidentally, the experiments were carried out with different qualities of coal, for the purpose of ascertaining their comparative economic effects.

Tht first series of experiments were made at the pumping engine at Rainton Colliery, which is well adapted for experiments of this kind, as the engine

* Institution of Mechanical Engineers.

is going continually at a uniform speed. The boilers are in one range, are all of the same size and description, and the temperature of the water was taken alike throughout. They are fitted with Juckes' mechanical fire-grate, consisting of an endless chain of short longitudinal bars, traversing forwards with a slow continuous motion, and thus conveying the fuel from the hopper by a self-acting operation. Nos. 1 and 2 were covered with one description of boiler-covering composition, and were fired by Juckes' mechanical furnaces, 4ft. broad; while two wrought-iron pipes, 2in. in diameter, were placed on the inner end, 1½in. above the bars. These pipes were necessarily exposed to the action of the furnace heat, and, in order to prevent them from being burnt, were constantly kept filled with water; Nos. 3, 4, and 5 boilers were also fired by Juckes' furnaces, to which were added Coulson's water boxes. These are the full length of the furnaces, 7in. square, made of ½in. wrought iron; on the inner end they are connected with the boiler by pipes, and have at the outer end a sludge pipe, to remove any scale from the boiler. Nos. 3 and 5 boilers are covered with different kinds of boiler-covering composition, whilst No. 4 is not covered at all. The height of the bottom of the boilers above the fire-bars was 2ft. in three of the boilers, and 1ft. 6in. in the others. The quality of coal used was "peas" or screened small steam coal; the same quality being used in all the experiments, and the exact quantity of coal used was carefully noted. The time taken in consuming the coals was also noted, together with the number of gallons passed through the special feed pipe; all connection with the other boilers being shut off. The strokes of the engine were also taken during each experiment by means of engine counters. The result of these experiments may be generally stated to be:—

	lb. of water evaporated per lb. of fuel.
1st.—With boiler covering, without water boxes, and with boilers 2ft. above fire-grate	4·83
2nd.—Without boiler covering, with water boxes, and boiler at 1ft. 6in. above fire-grate	4·66
3rd.—With boiler covering, with water boxes 1ft. 6in. above fire-grate	5·02
4th.—With boiler covering, with water boxes 2ft. above fire-grate	5·38

The advantages of water boxes in increasing the evaporative power of a boiler, as well as in the increased economy of fuel, are therefore very considerable; but those advantages are to a great extent neutralised by the difficulties and increased expense in upholding those boxes. There might be circumstances, however, when their use would be attended by ultimate economy. The advantage of having the boilers at a distance of 2ft. above the fire-grate, as compared with 1ft. 6in., is also shown by these experiments. With 1ft. 6in. distance the effect was 5·02, as compared with 5·38 with a distance of 2ft., showing an advantage in the latter of more than 6 per cent. It is also found in practice that the boiler is much less injured by the action of the heat at the greater distance. The second series of experiments was made with the range of boilers of the Seaham winding engine, and they are under cover of a boiler-house. The boilers are all of the same dimensions, being ordinary egg-ended cylindrical boilers, with a straight flash flue going into the main flue. No. 1 boiler was fired by hand; the heated air, after passing along below the boiler, returns by a side passage, and travels all round the boilers before entering into the chimney. After the wheel flue experiments were made, the flue of this kind was made into a straight flash flue. No. 2 boiler was first fired by hand, with a straight flash flue running direct into the main flue, and was afterwards fitted up with Stanley's self-feeding mechanical furnace. No. 3 boiler was fired with Vicar's self-feeding furnace. Nos. 4 and 5 boilers were fired with Juckes' furnace, of the same description as those already experimented on at the Rainton Colliery pumping engine.

From the experiments the following deductions may be drawn:—First, with hand firing the quantity of water evaporated per pound of coal, with a flash flue, is 6·66lb., as compared with 5·22lb. with a wheel flue; and the total quantity of water evaporated is 441 gallons per hour, as compared with 433 gallons per hour, showing the marked advantage of the flash flue over the wheel flue, not only in economic effect of fuel, but also of boiler space. It is probable, however, that this amount of economic effect (6·66) is considerably higher than that obtained under ordinary circumstances, as the fires were more regularly attended to than is usual with hand firing. Secondly, Juckes' furnaces. This apparatus, invented for firing steam boilers, has been in operation for some time in this district, and has lately been adopted very largely at many collieries in the North of England. The advantages of this furnace are, perfect combustion of smoke and great regularity in raising steam; the saving, in common with other mechanical appliances, in the wear and tear of boilers, and in manual labour in stoking, the latter amounting probably to £200 per year per boiler. In comparison with hand firing, it does not seem to possess any great advantage in economy of fuel, the comparative economic effect being 5·90 as compared with 6·66 for hand firing; but the latter is probably a much higher result than what is usually attained in practice. Like all other mechanical appliances, it requires a certain amount of care and attention in its use, but on the whole it may be said to be successful and economic in application. It is not well adapted for using Duff coal, although this is done in some instances when the Duff is washed.

Thirdly, Vicar's furnaces. Of all the mechanical apparatuses for firing steam boilers, none seem to be so successful as Vicar's, as arranged at Seaham Colliery—though this apparatus erected elsewhere seems not to have worked satisfactorily—which was probably owing to the improvements recently made in the apparatus. These now consist of three distinct appliances. The traversing bars, intended to give progressive motion to the incandescent fuel, by a slow alternate and intermittent longitudinal motion; secondly, the pump feeders, which alternately press a regular supply of coal from the hopper to the bars; thirdly, the water troughs in which the firebars are immersed, and which are absolutely essential, as no ordinary firebars can withstand the intense heat of the fire. This furnace was in constant operation at Seaham Collieries for nine months without requiring any repairs, and in all respects it has been most successful and economic. When using the same class of coal (peas) as in the hand-firing experiments, the economic effect was 7·14, as compared with 6·66; but the maximum results of this furnace have probably not yet been obtained, nor the best condition as to thickness of fire ascertained — the high amount of 8·78lb. of water evaporated per lb. of coal being in one instance obtained. This furnace is very efficient in its action in avoiding the formation of smoke. The great advantage, however, attending the use of the furnace is its applicability to the use of Duff coal, or dust coal, with high economic effect. It will be observed that with dust coal the economic effect actually reached 6·84lb. of water per lb. of coal. Taking the consumption of fuel in one of these experimental boilers at six tons per day of twenty-four hours, and taking the comparative price of peas and Duff coal at 3s. and 1s. per ton at the pit, the commercial economy effected by the use of these furnaces over any other mechanical apparatus not adapted to use Duff coal will be £200 per year per boiler. The evaporative power of the apparatus does not appear by these experiments to be equal to that of Juckes' or hand firing, although this may arise, as before stated, from the fact of its maximum power not being yet perfectly developed.

A somewhat interesting circumstance may be observed in these experiments. The firebars used in this special fire are 5ft. 4in. in length, whilst those in Juckes' apparatus are 6ft. 6in. in length; but although the heat of the fire in Vicar's grate was much more intense than in the Juckes', the pyrometric observations in the flue beyond the boiler invariably showed much lower temperature from the former than from the latter. It would seem, therefore, that the heat developed on the Vicar's grates is of a considerably higher intensity than that of the Juckes, and as effectual in its action on the exposed surface of the boiler, so that the absolute heat remaining on arriving at the flue is then reduced below that of Juckes. The experiments with Stanley's apparatus give very irregular results, showing that a lengthened series of experiments as to speed of dispersers, thickness of fire, &c., would be required before the maximum effect could be regularly attained. In this apparatus the coal falls through crushing rollers on to two dispersers or rapidly revolving discs with radiating ribs, which scatter the coal uniformly through the fire by centrifugal action. The advantages of this furnace are that it permits of the use of Duff or dust coal, and a comparatively large amount of fuel can be consumed per square foot of firegrate surface. As compared with hand firing, a much lower economic effect is exhibited, being 4·74 against 6·66; but it is more than probable that this arises from the Stanley apparatus not being in all respects arranged to obtain its maximum effects. A few experiments were made with this furnace after the addition of Whittaker's traversing bars, but not sufficient to yield any reliable data. The third series of experiments with single tubular boilers were made with two boilers erected at Silksworth Colliery for temporary purposes, which were fortunately of exactly the same size, and were constructed with a single tube. They had been previously in use at the Londonderry blast furnaces blowing engine, and were then set over the firegrate, the draught returning through the tube and thence round each side of the boiler. At Silksworth, one of these boilers is set in a similar way, the other having a firegrate fitted up in the tube and used as a Cornish boiler.

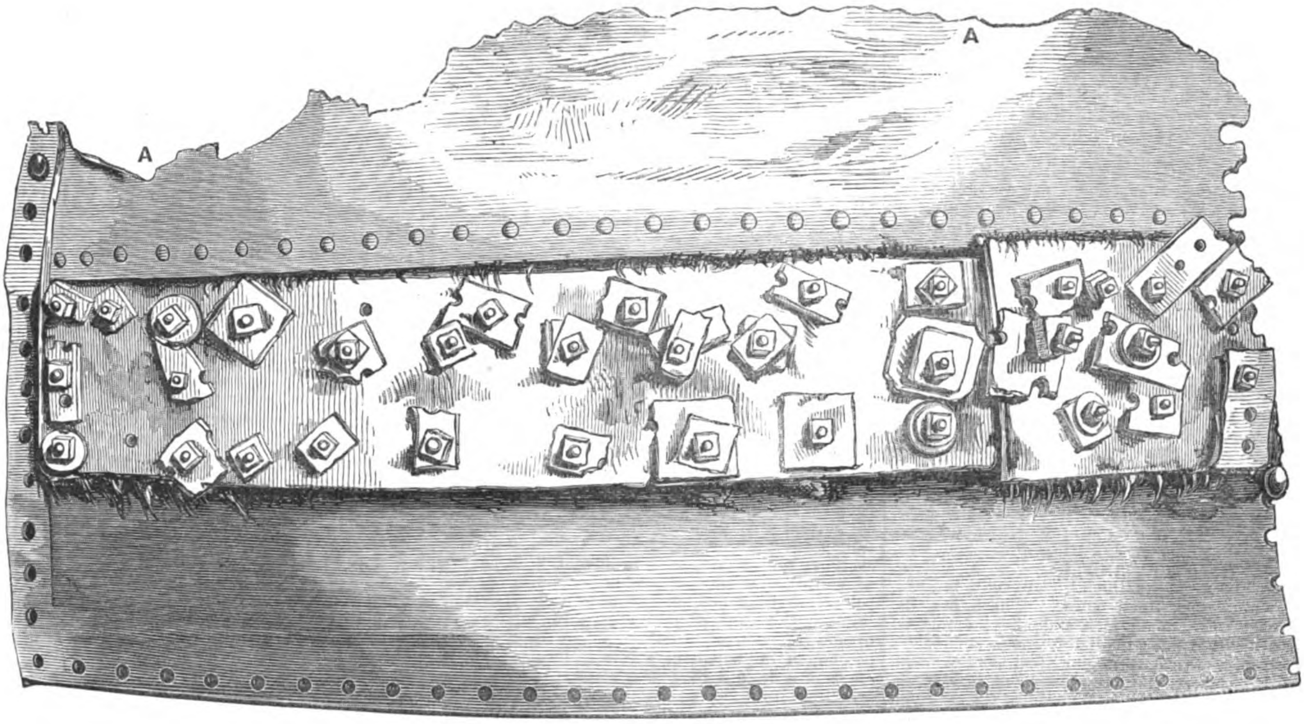
This series of experiments was intended also to show the useful effects of external heating surface, and, by an arrangement of dampers, the smoke could either be taken at once up the chimney or made to pass all round the outside of the boilers by the external wheel flue. The following are the chief deductions to be drawn from these experiments:— 1. The advantage, in No. 1 boiler, of using the wheel flue, overtaking the smoke direct through the tube to the chimney, is as 5·51 to 4·87. 2. There is a slight disadvantage in No. 2 boiler using the return tube through the boiler and side flues, instead of taking the flame direct from under the boiler to the chimney—being as 4·72 to 4·94. The general results of these experiments tend to show the advantage of flash flues having the usual large heating surface. The most important point, however, to be deduced from the experiments was the small evaporative power of the boilers when fired through a single tube, as compared with the result of firing underneath the boilers, being only 604 and 690 gallons evaporated by the former as compared with 1,344 and 1,243 by the last method, the economy of fuel being about the same in each case. The chimney, however, used for these boilers was only temporary, and not capable of producing a draught sufficient for the wheel flues. This fact renders it impossible to make any comparison between these experiments and those made at Seaham Colliery. It must be borne in mind that these boilers are by no means fair specimens of the Cornish boiler; and arrangements are being made to carry out a series of experiments to ascertain the evaporative power and economy of the Cornish boiler as compared with cylindrical boilers. These experiments will be made with boilers recently erected at Hetton Colliery on improved construction.

PRODUCTION OF SUGAR.

MR. ALFRED FRYER, of Manchester, who it will be remembered has introduced some important improvements in sugar-producing apparatus, has recently patented some improvements which extend from the apparatus used in the transport of cane or beetroot from the field to the factory up to and including that used for the extraction and subsequent treatment of the juice. Mr. Fryer's improvements in transport have for their object the combination of the loading of the canes or beets at once upon the cart which shall convey them to the crushing mill or rasp with the use of tramroads of narrow gauge, and therefore of comparatively small cost. For this purpose he constructs a truck of metal, and furnished with only two wheels keyed fast upon their axle. This axle projects through the wheels on each side, and at each end of it is placed a bracket resting in a bearing upon it and hanging down nearly to the lowest part of the circumference of the wheel. Each of these brackets terminates on the outer side in a flange or step, which is prolonged in such a manner that by slightly inclining the bracket its edge comes in contact with the ground. When in this position the wheels of the cart containing the canes or beetroot can be drawn on to these flanges, where when the brackets are again brought to a vertical position they rest, and the carts thus freed from the ground and resting on the trucks are drawn along the tramway. Several of these carts are formed into a train, the fore part of the one being supported by the hinder part of the adjoining one.

When canes are being operated upon by a mill the pressed cane or megass contains a consider-

CORRODED BOILER PLATE AND BOLTED PATCH.



able percentage of unextracted juice. In order to obtain as much as possible of this saccharine matter, Mr. Fryer subjects the megass to repeated pressure under water by means of an apparatus which he calls the affusor. This consists of a series of rollers revolved synchronously and arranged in an upper and an under row. The megass is passed between these rows, and is pressed as it passes between each roller and the one adjacent to it. These rollers are fitted into a vessel containing water, which is heated. The rollers and water level are so arranged that the greater number of the points of contact between the rollers are under the water level, whilst a smaller number are above it, so that the megass is first squeezed under water and then as much as possible of the moisture is wrung out from the affused megass. Water is introduced into this vessel near the end from which the megass emerges, and the sweetened water is drawn off at the opposite end, where it contains the greatest proportion of sugar.

As the megass is now divested of most of its sugar, and as it still contains a considerable quantity of moisture, it is next taken by means of a megass carrier of the ordinary construction to a megass drying oven, where the moisture is removed sufficiently to admit of the megass being used at once with advantage as fuel. This oven consists of a lofty chamber, constructed of brick or stone. The megass is delivered by the megass carrier upon the top of this chamber, and there falls upon trapdoors, which are opened at intervals, and thus permit the megass to slip down upon another series of trapdoors placed immediately below them, which on being opened in their turn permit the megass to pass down into the oven. As one set of these trapdoors is kept shut whilst the other is open no current of cold air is drawn into the oven. The megass thus admitted to the oven falls upon shelves, each of which is suspended by its two ends in such a way that it can easily revolve or reciprocate so as to allow the megass to slip or fall off on to the next lower shelf. The megass thus falling from shelf to shelf, resting for awhile upon each, falls at last upon the bottom of the oven, whence it is taken by a travelling belt to the several furnaces, where it is to be used as fuel. In the oven the megass is dried by means of the waste products of combustion from the furnaces of the factory being drawn through it.

In order to use to the best advantage for steam raising purposes the long clear flame of dried megass Mr. Fryer makes use of a long boiler of small diameter, which is placed at an inclination in such a way that for a great part of its length the whole of the circumference of the boiler is exposed to the flame, while at the same time no flame is allowed to play upon the boiler above the water level. In cases where Mr. Fryer's patent concretor* is the apparatus used for concentrating saccharine juice, and where more than one concretor is employed, so that a common chimney is used for several furnaces, the air heating chamber is constructed in such a way that the products of combustion after ascending through a certain number of the tubes of the air heater as at present arranged are caused to descend through another certain number, and are then conducted into an underground flue leading to the common chimney. In some cases, chiefly where only a single concretor is used, and where megass is the fuel employed, a boiler such as already described is placed underneath the trays of the concretor in such a manner that the waste heat of the boiler furnace after heating the boiler will pass through the air heater of the concretor. The top of the boiler thus placed forms a part of the bottom of the flue of the concretor, thus utilising to this extent heat which would be otherwise radiated and lost. In other cases the boiler is placed at the side of the trays instead of underneath them.

* For an illustrated description of this apparatus see the MECHANICS' MAGAZINE for January 19, 1866.

REPAIRING BOILERS WITH BOLTED PATCHES.

It has occasionally fallen to our lot to expose the unskilful manner in which boilers are sometimes repaired, but never have we come across such a gross outrage upon boiler repairing as in the instance we are about to notice. Indeed, so flagrant is the case that one might almost be disposed to accept it as a caricature were it not authenticated by Mr. Fletcher, the Engineer-in-Chief to the Manchester Steam Users' Association. The explosion which exposed the wretched piece of patchwork occurred at a small steam forge on the 16th of July last, and resulted in the death of one person, as well as in serious injury to four others. The boiler in question was of the plain cylindrical, egg-ended, externally-fired class, and measured about 21ft. in length by 4ft. 6in. in diameter, while the thickness of the plates was as nearly as may be three-eighths of an inch, and the ordinary working pressure about 50lb. on the square inch.

It appears that about a year before the explosion, the attendant had discovered a flaw on one side of the boiler, which he repaired in the following unsatisfactory manner. Instead of having the defective part cut out and a new plate securely riveted to the boiler, he laid a patch about 4ft. 8in. long by 9in. wide on the outside of the boiler over the defective part and in a horizontal direction, while he laid another patch of very similar dimensions inside the boiler immediately under the outer one, passing a number of bolts, amounting in all to 37, through the three thicknesses, and laying between each of the patches and the boiler plate a layer, about half an inch thick, of hemp, or felt, or something very similar, in order to make the whole steam and water tight. To accommodate the length of the bolts to the three thicknesses of plate and two thicknesses of padding, 49 rough and irregularly shaped bits of iron were put under the nuts as washers, so that the whole presented the most unmechanical and clumsy appearance, looking far more like a relic from the scrap heap than a portion of a boiler worked at a pressure of 50lb. on the square inch, and on the integrity of which the safety of life and limb depended. Such a patch, or rather plaster, proved, as might be expected, anything but effective. The boiler kept on leaking, and the water trickled down upon a longitudinal seam of rivets just below, eating the heads off on its way, and also thinning the plate a few inches lower down, where it was covered by the brickwork forming the top of one of the side flues, until it was reduced for a length of upwards of four feet to the thickness of a sheet of paper, in consequence of which the boiler burst, simply from loss of metal.

No description, however, can do justice to this corroded plate and bolted patch. They must be seen to be realised. But we have appended an engraving made from Mr. Fletcher's drawings which may give some little idea. The padding used for making the joint steam-tight may be seen in this cut oozing out at places from between the patch and the boiler, while there may also be seen at each side of this patch a long groove eaten into the boiler by the persistent leakage, the jagged line A A representing the primary horizontal rent where the plate was reduced to the thickness of a sheet of paper. It is scarcely necessary to point out that had this boiler been under inspection such a piece of patchwork, and such a dangerously-wasted plate, would have been at once condemned, and the explosion prevented.

AT the meeting of the Common Council held yesterday Mr. Deputy Lowman Taylor, chairman of the Markets' Improvement Committee, will present a report from them, recommending that they be authorised to prepare and prosecute a Bill in Parliament for extending Charterhouse-street into Aldersgate-street, through Charterhouse-square, and also to take powers to widen Long-lane on the northern side, the cost of such improvements to be charged upon the tolls of the Metropolitan Meat and Poultry Market, and also for authority to apply to Parliament for the toll at the market to be increased at once, instead of at the end of four years from the present time, and to give the necessary notices accordingly.

THE BRITISH NAVY.

On the 1st inst. we had 258 vessels in commission, including coast-guard ships and their tenders. Among the steam vessels were 23 armour-plated ships, 1 floating battery, 5 Indian troop ships, 5 ordinary troop ships, 31 rated vessels, 1 block ship, 19 sloops, 31 gun vessels, 15 gun boats, 3 Royal yachts, 4 vessels employed on surveying service, &c. There were also 39 sailing vessels, principally employed in harbour service. The whole of these ships and vessels were manned by 35,932 men, and an armament of 2,230 guns. The total nominal horse-power was 56,235 and 313,076. These vessels were stationed as follows:—One at Woolwich of 1,069 tons, mounting 42 guns, having a complement of 67 officers and men, 23 marines and 1 boy, making a total of 91. At Sheerness there were 3 ships with a total of 2,109 tons, armament 25 guns and a nominal horse-power of 352, having a complement of 393 officers and men, 179 marines and 5 boys; in all 577. At Portsmouth there were 19 ships, 23,219 tons, armament, 112 guns, and nominal horse-power 1,835, having a complement of 1.501 officers and men, 435 marines, and 91 boys; in all 2,027. At Devonport there were 13 ships, having a tonnage of 17,245, armament 203 guns, and nominal horse-power 260, with a complement of 988 officers and men, 366 marines, and 63 boys; in all 1,417. At Pembroke there was 1 ship, the "Nankin," of 2,049 tons, having a complement of 59 officers and men, and 3 marines. At Queenstown there were 4 vessels, mounting 40 guns, of a total nominal horse-power of 1,120, and 4,307 tons, with a complement of 246 officers and men, 68 marines, and 1 boy; in all 315.

The total tonnage of the 3 Royal yachts is 2,834, with 800 nominal horse-power. There are 123 officers and men, 27 marines, and 6 boys employed on board these yachts; in all 156.

The 8 ships which form our Channel Squadron mount 161 guns, the total tonnage is 41,211, and they have a nominal horse-power of 8,850. The total complement of all the ships' companies is 4,674, viz., 3,497 officers and men, 828 marines, and 349 boys.

On the Australian station we have the smallest, and on the China station the largest squadron, as we shall presently show.

In the Mediterranean we have 17 vessels, of 6,020 nominal horse-power, an armament of 141 guns, and 28,772 tons; with a complement of 2,970 officers and men, 659 marines, and 323 boys; making a total of 3,952.

On the North America and West India station there are 21 ships, having a nominal horse-power of 5,370, an armament of 216 guns, and tonnage of 27,979; with 2,380 officers and men, 563 marines, and 282 boys; making in all 3,230.

In the Brazils it will be seen that we have not only considerably reduced the squadron, but placed it under the command of a captain; heretofore it has been a flag officer's command. On the station there are 5 vessels, having a nominal horse-power of 670, carrying 34 guns, and a tonnage of 4,418, and manned by 428 officers and men, 94 marines, and 54 boys; making a total complement of 576.

In the East Indies there are 6 vessels, with a nominal horse-power of 1,710, having a tonnage of 7,575, and an armament of 55 guns; the complement of officers and men is 961, marines, 194, and boys, 128; in all 1,283. On the Cape of Good Hope and West Coast of Africa station we have 13 vessels, of a total tonnage of 12,022, nominal horse-power 1,934, and an armament of 64 guns, with a complement of 1,066 officers and men, 237 marines, and 121 boys, making a total of 1,424.

In the Pacific there are 10 vessels, having a nominal horse-power of 2,680, mounting 97 guns, and tonnage of 12,240, with a complement of 1,401 officers and men, 361 marines, and 201 boys; in all 1,963 hands. On the China and Japan station there are 27 vessels, having a tonnage of 20,871, nominal horse-power 4,180, and an armament of 123 guns, with a complement of 2,177 officers and men, 378 marines, and 202 boys; making a total of 2,757. On the Australian station we have only 4 vessels, with 1,120 nominal horse-power, 4,462 tons, and an armament of 33 guns; there are 558 officers and men serving in this squadron, as well as 109 marines and 108 boys; making a total of 775.

In the flying squadron, troop service, store service, &c., including the "Galatea," which latter is commanded by his Royal Highness the Duke of Edinburgh, we have 18 vessels in commission, with a total tonnage of 38,035, and 8,170 nominal horse-power, carrying an armament of 232 guns. In these services there are 4,011 officers and men, 713 marines, and 463 boys, making a total of 5,187. There are 4 vessels employed on the surveying service, having a nominal horse-power of 462, and 1,988 tons, mounting 17 guns, with a complement of 269 officers and men, 115 marines, and 19 boys; in all 326. In the Coast-guard service there are 55 vessels, including cruisers, manned by 3,597 hands, 2,391 of which are officers and men, 885 marines, and 321 boys. The total tonnage of the Coast-guard ships is 37,276, having a nominal horse-power of 7,620 and an armament of 307 guns. There are also 10 drill ships for the naval reserve, with a tonnage of 10,403, horse-power 120, and an armament of 138 guns, having a total complement of 29? officers and men. In addition to these there are 14 flag officers, who with their retinues make up a total of 219. Also 3,103 supernumerary commissioned officers, engineers, warrant officers, &c., and 18 marines in reserve and gunnery ships; 19 supernumerary officers and men, and 4 marines in flag ships abroad, and 243 kroomen. In our iron-clads alone we have 11,514 officers and men. By the above it will be seen, by taking the different ports and stations, that we have 30,876 officers and men, 6,553 marines, and 5,887 boys (exclusive of the officers and men employed in the Indian troop service, and about 3,500 supernumerary petty officers, seamen, and boys, borne on the books of the receiving ships at the home ports for disposal).—"Standard."

AN INVENTIVE PEOPLE.

Yankee origination is universal and ubiquitous. Fourteen thousand patents will, it is estimated, be granted by the United States office this year, and two applications are rejected for every one granted. Over forty thousand specifications lodged in a year, and this in the States only! Take up the patent journals of any country in the world, says the "Gentleman's Magazine," and you will find a good percentage of inventions of American origin. In that country of geniuses everybody invents. Said a patent commissioner, the other day, "Our merchants invent, our schoolmasters invent, our soldiers and sailors invent, our professional men invent—aye, even our women and children invent." True; and wonderful schemes some of these amateurs propound. One man claimed protection for the application of the Lord's Prayer, repeated in a loud voice, to cure stammering; another applied for the envied parchment on behalf of a new and useful attachment of a weight to a cow's tail, to prevent her switching it during the milking operation; another proposed to cure worms by fishing for them with a delicate line and tiny hook, baited with a seducting pill; while a lady patented a hair-crimping pin, which she specified might also be used as a paper cutter, as a skirt supporter, a child's pin, a bouquet holder, a shawl fastener, or as a book mark. These were cases cited by Mr. Fisher, the commissioner aforesaid, in a recent address to the American Institute. Since this was delivered, I have read of patents for a "horse-refresher" (a hollow bit, perforated with holes, and connected by a flexible tube with a water reservoir in the vehicle, so that the driver can give his animal a drink without stopping), and a luxurious contrivance called "The Snorer's Friend," a device to be attached to church pew backs, to form a comfortable head-rest, enabling the owner to sleep through the dullest sermon in peace and quietness.

ROGERS' PATENT PROJECTILE ANCHOR.

As a proof of the very great attention which the present Board of Admiralty devote to inventions which might be useful, not only for the purposes of war but for saving life, we "Hampshire Telegraph," may mention that Mr. J. Banting Rogers, of 70, Andrew's-road, Hastings, wrote to their lordships on the 7th of July, asking that he might be allowed to make experiments with models of his patent projectile anchor, non-choking block, and rove rope, in the perfection of which he has been long engaged. A reply in the affirmative came on the 10th (three days following), and on the 20th and 21st of the same month experiments were made at Sheerness in the presence of several naval captains and other officials, and proved very successful. On the 12th of August Mr. Rogers received instructions to put himself in communication with Captain Henry Boys, of H.M. gunnery ship "Excellent," and to make an anchor and block in Portsmouth dockyard of the same size as that intended by the invention, all expenses being defrayed by the Admiralty, except Mr. Rogers' personal expenses, as no terms at present could be made. Acting upon this intimation, no time was lost in getting to work, and we understand that in a very short time an experiment will be made on board the "Excellent" by the authorities. The anchor, which, besides the use to which it may be applied in navigation, is doubly valuable as a means of saving life from wrecked vessels, consists of a tri-fluked hinged or folding anchor, weighing about 112lb., so contrived that it can be fired from a mortar or other piece of ordnance. Attached to the anchor is a block of a peculiar make, which will not choke with sea-weed, and will allow knots and kinks to pass freely through it. Through the block passes a "rove rope," or double line, the two ends of which being attached on shore are used to haul out a similar double line of cable of sufficient strength. By means of this arrangement the anchor may be flung into the sea with the rope attached, the lifeboat may be drawn through the surf, and her crew thus enabled to pull her to the ship without the exhaustion of getting her off, a process often found impossible, even in cases where the lifeboat could be managed with ease were she once outside the shore surf. A cone and block may also be thrown across the ship with the almost unerring aim of the mortar, carrying with it the double or endless rope, by means of which instant and continuous communication is established to the shore, life belts, &c., conveyed to the crew, and by which they may be drawn to the shore without exertion on their part. The contrivance will be found equally serviceable to those on board ship, for the anchor can, of course, be fired as well from the ship to the shore as *vice versa*, so that in the case of a ship stranding facilities would be afforded for the men on board to make communication with very much more certainty than at present. The rope attached to the anchor block is protected from being injured by the charge in the mortar by a metal cap, while to prevent the rope becoming entangled, it is "paid out" from boxes, in which it has been previously arranged according to another of Mr. Rogers' inventions. Each of the numerous experiments made with models of the apparatus hitherto has been eminently successful, and the inventor has received various medals and presents from philanthropic societies, together with the sensible prize of £50 from the Shipwrecked Mariners' Society for experiments with the anchor at the Crystal Palace in June of last year.

MICA BROCADES—A NEW PRODUCT OF ART

No doubt all of our readers are acquainted with the mica which is so extensively used in doors of stoves. But it may be stated that under this term a whole group of minerals is comprised, either occurring massive or disseminated in rocks. They have all a more or less foliated structure and pearly lustre. They are elastic, transparent or translucent, and have a specific weight of 2·7. In Germany mica has recently found application for the production of bronze-like colours which bear the names "brocades," "crystal colours," and "mica bronzes." The mineral is to this end well crushed, boiled in hydrochloric acid, then washed with water, and assorted according to the size of the laminæ. Mica scales thus obtained exhibit a glass-like lustre combined with a silver-white appearance. The advantages of these brocades (which by the way may be coloured) over the ordinary metallic brocades, are stated in the "Scientific American" to be the following:—1. They do not contain any ingredient injurious to health. 2. They possess metallic lustre like the ordinary brocades, and some surpass them even in liveliness of colour. 3. Brown, black, blue, green, and rose are obtained in remarkable beauty, which is not the case with the metal bronzes. 4. They comport themselves with perfect neutrality toward sulphurous exhalations. 5. Their specific weight being very slight, their yield is consequently correspondingly great. In the application they may be fixed upon all kinds of articles of metal, wood, glass, plaster-of-Paris, and paper board. They are consequently well adapted to the preparation of artificial flowers, fancy papers, sealing-wax, in tapestry, furniture-making, and painting. Theatres may employ them for imitating gold rain and snow, for which purpose they recommend themselves on account of their lightness and cheap price. In short, they may be used for almost all the purposes to which the ordinary bronze powders have been applied.

In fixing these brocades upon articles of any kind it is advisable to paint them first with a colour similar to that of the bronze; for silver, a ground of white lead is suitable; for blue, one of ultramarine, &c. They are equally suitable for oil and glue colours, which latter are fixed with a mixture of four parts of glue and one of glycerine. Upon this coat, when hard, the binding material for the brocade is spread, and after one quarter of an hour this latter is sifted over. As binding material a paste, consisting of four parts of boiled starch and one of glycerine, is recommended. If desirable, the powder may be finally pressed down with a roller. If the ground is formed by an oil paint, the binding material for the brocade should be constituted of a dammar, or pale copal varnish, upon which, when only pitchy, the powder is sifted over. When finally coated with a suitable spirit, dammar, or copal varnish, the so-prepared articles assume a lustre which, in beauty and durability, far surpasses any heretofore obtained with the common bronzes. When small particles of mica-silver are spread over articles coated with asphalte varnish, the result is a good imitation of granite. The crystal colours are also suitable for calico printing, and fabrics upon which they are applied surpass in brilliancy the heavy bronze and glass-dust fancy fabrics from Lyons. Employed between or on coloured gelatine plates, they give rise to superb crystallizations, which are used as inlayings for buttons and various other articles. They may be spread over finished porcelain and glassware, if these are heated again to the fusing point of their glazing.

According to Dr. C. Cech and L. Schneider, in Prague, these brocades may be coloured with the following dye-stuffs:—Rose, with a decoction of cochineal; cramoisin, with the bluish magenta red; bright red, with fuchsine and Havana brown; violet, with Hofman's violet. A solution of Prussian blue in oxalic acid serves for producing a bright blue, and Girard's violet for deep blue; light and dark

green are imparted by aniline green and curcuma gold with curcuma, dark brown with a proper bark extract, and black with litmus and hæmatoxylin or logwood extract. Silver needs no colour. According to Dr. L. Feutchwanger's (vide his popular "Treatise on Gems"), mica is found at Williamsburg, Mass., Hartford, Conn., and many other places. The green mica, which is of a beautiful grass-green colour, is found in Brunswick, Me. The rose-red mica, which is also a very beautiful mineral, is principally found at Goshen, Chesterfield, Mass., Acworth, N. H., Bellows' Falls, Vt., &c. Mica, according to the above-named mineralogist, when of good colours, may be used for jewellery and other ornaments.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, November 18.)

THE vitality displayed in the chemical market of late shows no signs of abatement, and prices are very firm: the alkali trade shares to some extent in the increased business, though prices are not remunerative. In minerals somewhat more activity has been felt, and values in a few instances have advanced. In the metal market a considerable trade has been done in pig iron, and prices during the week advanced, but have closed weaker. All other metals are stationary, with a moderate demand, excepting tin, in which a reduction has taken place. Soda: in soda ash and caustic soda a considerable business has been done at prices ranging from £7 to £7 5s. per ton for the former for 48; and at £13 5s. to £13 10s. per ton for the latter for 60. Crystals inactive, at £3 15s. to £4. In bi-carbonate there has been little doing, at £9 10s. Nitrate of soda: falling to 15s. per cwt., and slightly under during the week, is held at 15s. 6d. to 16s. for the present. Potash: muriates are still wanted, and obtain £7 5s. to £7 7s. 6d. for 80. Saltpetre: no business done, and values unaltered. Alum: meets with a steady sale at £6 5s. for loose lump, £7 in export barrels, and £7 for ground. Ammonia: sulphate has reached the highest point it is likely to obtain, £17 10s. for finest white, and is somewhat more plentiful. Grey obtains a ready sale at £16 to £17. Copperas: no great business reported in green, at 52s. For dry there is a steadily increasing demand at 50s. Chloride of iron obtainable at 52s. Pyrites: in ordinary request, at 6½d. to 7½d. per unit. Calcined still sells at 44s. R.C. Lime: a fair business in phosphates at 52s. 6d. for 65. Bleaching powder in continued brisk demand at £8 5s. to £8 7s. 6d. for 35. Disinfectants find an active market at 5s. 3d. per cwt. for the best quality. Manganese: is still rather dull. Prices unaltered, at 95s. for 70. Acids: tartaric in request at 1s. 1½d. for foreign; English ground, 1s. 2½d.; citric, 2s. 5d.; oxalic, without much sale, at 7½d.

METALS.—Iron: Scotch pigs selling freely at 54s. 4d. to 54s. 6d., closing steady. Cleveland advanced to 45s. 6d. for forge, and 50s. 6d. for No. 1. Welsh bars, £6 10s. to £6 15s.; Staffordshire, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: is rather firmer. English tough, £72 to £73; Chili Slab, £68 to £69. Tin: prices are quite nominal. English ingots, £122 to £123; Straits, £118 to £120. Lead: in good inquiry, and prices have advanced. P.G. best English soft pig lead, £19. Spelter: quiet. English, £20 10s.; Silesian, special brands, £19 15s. to £20; Hard spelter, for export, £16 5s. to £16 10s.

Legal Intelligence.

COURT OF COMMON PLEAS.

NOVEMBER 13.

(Sittings in Banco, before Lord Chief Justice BOVILL, and Justices WILLES and KEATING.)

TATHAM v. DANIA.

THE plaintiff in this case was patentee of an improvement in machines for tearing and opening textile fabrics, which are popularly known in Lancashire as "devils." The action was to recover damages for an infringement of the patent, and at the trial before Mr. Justice Lush at the last spring assizes at Manchester the verdict was for the plaintiff upon all the issues; subsequently a rule was obtained to show cause why the verdict should not be entered for the defendant, or why there should not be a new trial upon various points, but the principal contest between the parties was whether the plaintiff's invention was such as could form the subject of a patent. The mode in which the cotton waste and other materials were torn up so that they could be spun and woven again, was by passing them under rollers set with teeth, the substance being carried on from one roller to another until the operation was complete. The essence of the plaintiff's invention was, that he had contrived a chamber or recess between each two rollers, in which chamber the material was collected, accumulated, and condensed prior to being passed on to the next roller. The rollers were in use prior to the patent, but it was said that the condensing chamber was a very valuable improvement in the machines.

On the present occasion cause was shown against the rule being made absolute. The case occupied the best part of the day, and was concluded on the 16th.

Mr. Holker, Q.C., and Mr. Aston showed cause against the rule, and Mr. Manisty, Q.C., and Mr. Edwards appeared in support of it.

The Lord Chief Justice, in delivering judgment, said that the specification was too wide. It sought to claim both what was new and what was old; and what it claimed as new, even if the subject of a patent, was not distinguished from the claim for that part of the patent which was admitted to be old. The only novelty consisted in running a pair of rollers formerly in use, at a greater velocity than certain other rollers. It appeared to him that it was very doubtful whether this, as claimed, was the subject of a patent, as it was a process perfectly well known, and in use in many kinds of machines.

Mr. Justice Willes and Mr. Justice Keating concurred, and judgment was given for the defendant.

COURT OF QUEEN'S BENCH, WESTMINSTER.

NOVEMBER 13.

(Sittings in Banco, before the LORD CHIEF JUSTICE, Mr. Justice MELLOR, and Mr. Justice HANNEN.)

DAW v. CARTER.

THIS was a question under the Gunpowder Act (23 and 24 Vict., c. 139) as to what is "ammunition" within the Act. It arose thus:—The appellant, Mr. Daw, the well-known gun-maker, had been convicted for keeping more than 5lb. of ammunition at a time at a place half a mile from his shop in Threadneedle-street without a licence for it. He kept powder there for the purpose of making cartridges, and he had more than 5lb. of cartridges at the store, for which he was convicted of having more than 5lb. of powder in cartridges. There were several convictions for the offence. There was a clause that a cartridge manufacturer might keep 200lb. of cartridges.

Mr. Archibald was in support of the conviction; Mr. Metcalfe was against it.

The Court affirmed the convictions.

VICE CHANCELLOR'S COURT.

NOVEMBER 17.

(Before Sir R. MALINS.)

POUPARD v. FARDELL.

IN this cause, which was noticed by us last week, the plaintiff by his bill sought for an injunction to restrain the defendant from infringing his patent, which he obtained for the manufacture of a skid or shoe for vehicles, and which article was largely used by omnibuses and other carriages. The case has lasted several days, several witnesses on each side having to be cross-examined.

The Vice Chancellor now said, at the conclusion of the arguments, that the evidence was very conflicting, but, looking at the length of time that the plaintiff had enjoyed his patent, he was of opinion that he had shown that his "skid" was a novelty, and that his specification was sufficient, and his Honour granted a perpetual injunction, with damages and costs against the defendant.

Mr. Glasse, Q.C., and Mr. Bovill were for the plaintiff; and Mr. W. W. Mackeson, Q.C., Mr. Stevens, and Mr. W. W. Cooper were for the defendant.

Correspondence.

CAZAL'S ELECTRIC MOTOR.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Can you or any of your readers kindly favour me with particulars of M. H. Cazal's electric motor for sewing machines?—I am, Sir, yours, &c., F. E. B.

THE HOLBORN VIADUCT BRIDGE.

SIR,—You will have seen what curious ideas the daily press is propagating about cracks in the piers under the girders of the new Viaduct bridge. The cause is very plain. The engineer has committed a great error in not placing an iron entablature along the top of the piers for the compound girders to rest on. The centre girders being long, and set on the top of each pier, the contraction would at once draw them inwards, and the next expansion would push them out and at once cause the cracks. There is no doubt the piers are strong enough to carry the weight, but when any sudden change of temperature arises, the sudden shocks will be too much for them. I am very sorry, for Mr. Haywood's sake; for, in all the years that I have superintended large works myself, I never remember to have seen better brickwork than that in the Viaduct. It is very clear that if the three spans had been equal, the top stone would in all probability have been split. An entablature of iron, with a roller under each end, however small, appears to me to be the only means of making it secure for the future.—I am, Sir, yours, &c., J. WALKER.

43, Mansell-street, November 15.

TRANSACTIONS OF THE INSTITUTION OF NAVAL ARCHITECTS.

SIR,—I was unaware of the trick which had been played upon me in making the despatch of the volumes of our "Transactions" an advertising medium for a comic periodical until I saw it exposed in your columns. I have taken measures which I hope will prevent this unfair practice in future.

The illustrations at the end of the volume are chiefly copper plates.—I am, Sir, yours, &c.,

C. W. MERRIFIELD, Hon. Sec.

9, Adelphi-terrace, London, November 15.

[We were very certain that the circular in question was not inserted with the knowledge of the executive of the Institute, and we are equally certain that they will visit with their displeasure the printer or binder who had the bad taste thus to puff some other job in which he is interested.—ED. M. M.]

NAVAL ENGINEERS.

SIR,—A friend of mine has recently received a letter (of which the enclosed is a partial copy) with a desire of the writer that it should be published, as showing some of the difficulties engineers have to contend with at sea, and how necessary it is that seagoing engineers should be practical men. If you can find a place for it in the MECHANICS' MAGAZINE, I shall be glad, as a subscriber since 1850, to see it there.—I am, Sir, yours, &c.,

ROBERT SHENTON.

9, Maria-street, Millwall, November 15.

The Telegraph Construction Company's steam ship "Investigator," Captain Knox, left Melbourne on June 16 at 10 a.m., steamed through Bass' Straits on the 18th, got under canvas and proceeded on her voyage for the United Kingdom, ran down to the 46th parallel, and had a prosperous voyage up to July 18, when, in consequence of heavy squalls and a heavy sea running, she broke her tiller about 7 p.m. The engineers fitted the spare tiller on at 9 p.m., and got her on her course again, and, on the following day, with furious squalls, a heavy sea struck her aft, and carried away rudder, after rudder post, and also the propeller, in which condition she lay helpless to the wind and waves for some days. Captain Knox rigged a spar over the stern until the engineer could make a temporary rudder. On July 28, the engineers went to work with a good will to weld together two stanchions about 3in. diameter, with a forge 2ft. square, and to rivet several pieces of plate iron together to make the rudder, which was finally shipped on August 8 after incredible labour on the part of the engineers. They had to contend against a heavy sea which was running all the time, and the ship at that date was 2,900 miles from the coast of Chili. The vessel was afterwards navigated with it, although the chief mate said he would rather be six months getting to port than the engineers should make one, and he would try all he could to carry it away. On Sunday, August 15, we made the land, but a thick fog coming down, the ship was put off shore until the weather might clear up. On the evening of the 16th, the ship was about 40 miles to north of this port (Valparaiso), and the steam ship "Zeta" passing at the time, Captain Knox went on board and arranged with Captain Walter to tow his ship into port, where she arrived on the 17th inst. at 5 p.m.

[We insert the above as showing what engineers are capable of doing when called upon in an emergency; although we hold it to be no more than an engineer—worthy to be so called—ought to be able to do. As to the statement about the chief mate wishing to carry the rudder away, we think no seaman would be such a flat, and we, therefore, give Mr. Shenton's friend credit for having mistaken the officer's meaning.—ED. M. M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Meetings for the Week.

TUES.—Institution of Civil Engineers.—Discussion upon M. Gaudard's paper on "The Strength and Resistance of Materials," and also on "The Public Works in the Province of Canterbury, New Zealand," by Mr. Edward Dobson, A.I.C.E., at 8 p.m.

Naval, Military, and Gunnery Items.

THE Pacific steamship "Magelican," from Liverpool for Valparaiso arrived out on the 25th of September, having accomplished the passage in 32 steaming days with a heavy cargo.

AN iron-clad frigate, the "Minine," was launched at Cronstadt a few days back in presence of the Emperor of Russia, the Cesarewitch, the Grand Dukes Alexis and Constantine, and the Prince of Oldenburg.

HER Majesty's iron-clads "Prince Consort" and "Royal Oak" ran ashore off Port Said on Monday last, but were got off without any damage whatever. The place where the occurrence took place was a bank of soft mud which has been formed outside the harbour by the excavations for the canal, and which is not marked on the chart.

THE Board of Trade have awarded a gold watch to Captain John Hawson, of the ship "Carlos," of Buenos Ayres, in acknowledgment of his humanity in receiving on board his vessel the master and crew, 31 persons in all, of the ship "Treasure Trove," of Liverpool, which was burnt at sea in lat. 6.48 N., and long. 22.48 W., on the 7th of September, 1868.

AN additional number of iron shipwrights have just been entered at Chatham Dockyard for employment on board the armour-clad double turret ship "Cerberus," which is being rapidly brought forward for sea. She has had an additional iron deck placed on her, in order to enable her to be navigated to Australia, and she will also be masted. On her arrival at Melbourne she will have her temporary iron deck and bulwarks removed.

THE *fetes* in inauguration of the Suez Canal commenced on Saturday last by religious ceremonies in the open air, which were performed both by the Ulemas and the Catholic priests. The latter was concluded by a speech and a benediction from Monsignore Bauer, the almoner of the Empress Eugenie. Monsignore Bauer congratulated those present upon the completion of the work, and thanked the Khedive who had immortalised his reign by co-operation in one of the greatest undertakings that any century had produced.

THE work of attaching the 10in. armour-plates to the sides of the "Glatton," turret-ship, building in No. 2 dock in Chatham Dockyard, has been resumed, after some short stoppage from want of plates. A number of plates have been attached on the starboard side, and a few on the port side. The work of building has gone on well, in spite of the men being exposed to the weather—sometimes very inclement of late—as there is no roof over the dock. The next dock, in which the "Sultan," broadside iron ship, is building, has a temporary roof.

THE death is announced of Rear-Admiral Warden, C.B., senior officer on the coast of Ireland, which occurred on the 12th inst. at Queenstown, after a short illness. The deceased Admiral entered the service at an early age, and obtained his commission as lieutenant in September, 1828; was promoted to commander in 1838; and obtained post rank in July, 1845. He was commander of the "Medea," serving on the coast of Syria, in 1840; and was engaged on active service during the Russian war. He obtained the rank of Rear-Admiral on the 12th of September, 1863.

FURTHER trials for endurance, range, and accuracy of the first of the new class of 12in. 600-pounder rifled guns were made during last week at Shoeburyness. The 9in. rifled howitzer also had further trial after an alteration in the arrangement of the hydraulic buffer which is fitted to it to check the recoil. The Maxwell Indian bronze rifle field gun also had a very interesting trial for range and accuracy. After upwards of 2,600 previous rounds with service charges, the shooting made by it was very good, especially considering that the endurance this gun had sustained was equal to about half a century of active warfare.

A NEW iron ship of war, the "Audacious," has arrived at Pembroke from Glasgow. The "Audacious" was built by Messrs. Napier and Co., with engines of 800-horse power by Ravenhill and Hodgson. She has been sent to Pembroke for the purpose of being entirely sheathed over with teak wood to prevent the action of the water on the iron. She is a fine vessel, and is a sister ship to the "Iron Duke," now nearly ready for launching, of 3,464 tons burthen. The "Audacious" is on the twin-screw principle, and has two pairs of engines. On her passage to Pembroke, in a strong gale of wind, she averaged 11 knots.

THE "Sin Nanzing," a new paddle, built and engineered by Mr. J. Elder, of Glasgow, for the North China Steam Navigation Company, has made a favourable trial trip. The dimensions of the "Sin Nanzing" are:—Length between perpendiculars, 225ft.; beam, 32ft.; depth of hold to spar deck, 23ft. 3in. Her engines are on the compound principle, for which Messrs. Randolph, and Co., of Glasgow, have long been distinguished; they are diagonal and have four cylinders. Messrs. Randolph, Elder, and Co. have now made 73 sets of these engines, 22 being for paddle and 51 for screw steamers.

THE question whether Krupp or Armstrong guns are to be adopted for the Austrian navy is not yet settled, but it has been decided that the iron-clad "Lissa" shall be armed with a new 9-inch cast steel Krupp gun by next February, if the experiments now being made with it in the "Steinfeld," near Vienna, should prove satisfactory. This gun weighs 246 cwt., and is specially provided with an iron carriage for use on board ship. The projectile is a cast iron shell, which weighs when filled 244lb. The cartridges contain prismatic gunpowder, made in the Government factory at Wollersdorf, which is said to be equal to the productions of the best foreign manufacturers.

THE Committee of Inventions, which was established in the Royal Arsenal, Woolwich, on the abolition of the Ordnance Select Committee, has been amalgamated with the Director-General of Ordnance Department in the Arsenal. The officers constituting this department, to whom everything which formerly came under the cognizance of the two former committees, including all inventions and patents relating to the art of war, is referred, now consist of the following:—Major-Gen. J. H. Lefroy, Royal Artillery, F.R.S., Director of Ordnance; Col. T. W. Milward, C.B., Royal Artillery Aide-de-Camp to the Queen, Deputy Director of Ordnance; Col. E. Wray, C.B., Royal Artillery; Lieut.-Col. H. Heyman, Royal Artillery; Capt. T. A. J. Harrison, Royal Artillery; Capt. W. H. Noble, Royal Artillery, members; and Quartermaster H. Behenna, Royal Artillery, commissary.

Miscellanea.

THE Euston Terminus of the London and North-Western Railway, at Euston-square, is to be enlarged and considerably improved. The works will commence about the latter end of this month.

A SCHEME for a Canadian Pacific Railway appears in tee newspapers of the Dominion. The length of line is 2,500 miles, and the capital £200,000,000.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending November 13, was 1,833. Total number since the opening of the Museum, free daily (May 12, 1858), 1,680,292.

THE St. Petersburg Exhibition for 1870 will be confined to Russian produce and manufactures; it is national and not international, as has been stated in some publications. It is to open on the 27th May, and close on the 27th of July.

THE Minister of Finance in France has recommended that a gold coin, of the value of twenty-five francs, corresponding with our English sovereign, should be issued by the French Mint, and the Emperor Napoleon has approved of the proposal.

IT is now understood in the parliamentary profession that neither of the three rival Brighton schemes, about which so much has been said, will be proceeded with during the forthcoming session, but will be deferred till next, owing to circumstances over which the several projectros have no control.

AS the next meeting of the British Association is to be held in Liverpool, a meeting of Liverpool gentlemen, principally connected with the local learned societies, was recently held in the mayor's parlour, the mayor, J. Hubback, Esq., in the chair, to arrange for the formation of a local committee. It is probable that the meeting will be held next September in St. George's hall.

A MEETING of the thick coal masters (their district embracing Tipton and West of Dudley) was held in Birmingham on the 11th inst., and in consequence of the recent rise in the price of finished iron it was resolved to raise the wages of the colliers 6d. per ton; the price of coal to be raised 1s. per ton. This change to take effect in a fortnight from the date of the meeting.

THE London and North-Western Railway Company recently constructed a branch line running from their central station at Lime-street, Liverpool, to Bootle, running through the principal eastern suburbs of the town. This line is shortly to be opened for passenger traffic, and a notable feature will be the running, morning and evening, of workmen's trains at the uniform rate of one penny for any distance.

THE following is a return of the quantity of coal exported from Grimsby during October, 1869:—To Belgium, 722 tons; Denmark, 1,826; Egypt, 3,528; France, 5,509; Hanseatic Towns, 723; Holland, 612; India, British possessions, 533; Prussia, 3,017; Russia, 655; Norway, 211; Spain, 591; total, 19,444; coastwise, 2,218; total, 21,662 tons. Corresponding period, 1868, 26,081; coastwise, 3,234; total, 29,315. Decrease, 7,653 tons.

THE number of visitors to the South Kensington Museum during the week ending November 13, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,687; Meyrick and other galleries, 998; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,702; Meyrick and other galleries, 81; total, 13,468. Average of corresponding week in former years, 9,878. Total from opening of Museum, 8,944,764.

AT the opening ordinary general meeting of the Royal Institute of British Architects, session 1869–70, held on Monday, November 1, 1869, the President (Sir William Tite, M.P.) in the chair, the following gentlemen were balloted for and declared to be duly elected:—Edward Augustus Grunning (Associate), of 9, Gresham House, E.C., as Fellow; Ernest W. C. F. Schmidt, of 30, Great George-street, Westminster, as Associate.

THE Berlin-Potsdam-Magdeburg Railway Company has during the summer instituted a number of experiments with the pneumatic telegraph, as a means of enabling passengers to stop trains in case of necessity, and these have been so successful that all mail-trains on that line will henceforth be furnished with an apparatus of the kind. Should they realise the expectations formed of them, they will probably be employed on all North-German Railways.

AT the last weekly meeting of the Board of Works a report from the Works and General Purposes Committee stated that a constant supply of water to the metropolis was most desirable, and recommended that the chairman of the board should seek an interview with the Home Secretary and ascertain whether it is the intention of the Government to bring in a measure founded upon the report of the royal commission. The question was briefly discussed, but was subsequently adjourned to the 26th inst., it being agreed that the report should in the interim be printed and circulated.

THE first series of notices for various railway Bills in the next session, which were issued on Saturday, are remarkable for the large number of applications they contain for the abandonment of proposed lines. The South-Eastern Railway ask for power to abandon the construction of the extension line to Cranbrook, which was authorised five years since, and also the whole of the railways between Tenterden and Appledore, and Appledore and Snargate. The Great Northern Railway Company wish to abandon the Watford and Edgware line, an undertaking which was also authorised five years since, and similar powers are asked by the Lancashire and Yorkshire Railway Company with respect to a portion of the Ripponden branch.

ONE of the most successful meetings of the Royal Horticultural Society this season was held on Tuesday, in the Council-room, South Kensington. The chrysanthemums were extremely good, and cut specimens of the gigantic dahlia imperialis, from the gardens of the society at Chiswick, attracted much attention. Fruit and growing plants of macadamia ternifolia, a proteaceous plant from Australia, were sent by Messrs. E. G. Henderson and Sons. The nut was found to be peculiarly good, and free from all rancidity. Mr. W. Wilson Saunders, F.R.S., presided, and the following candidates were elected fellows:—Carlo Brunetti, James Cowell, Major-General Henry Charles B. Daubeney, Adam Forsyth, Mrs. Munt, &c.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1288, 1290, 1291, 1316, 1321, 1327

BUILDINGS AND BUILDING MATERIALS—1293, 1301, 1329

CHEMISTRY AND PHOTOGRAPHY—1277

CULTIVATION OF THE SOIL, including agricultural implements and machines—1266, 1272, 1273, 1318

ELECTRICAL APPARATUS—None

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1267, 1280, 1292, 1295, 1308, 1328

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1268, 1271, 1275, 1276, 1309

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1264, 1270, 1282, 1283, 1289, 1296, 1298, 1302, 1302, 1305, 1306, 1307, 1312, 1313, 1314

GENERAL MACHINERY—1261, 1263, 1274, 1284, 1294, 1325

LIGHTING, HEATING, AND VENTILATING—None

METALS, including apparatus for their manufacture—1317

MISCELLANEOUS—1262, 1265, 1278, 1297, 1304, 1310, 1311, 1320

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1269, 1279, 1281, 1286, 1299, 1300, 1322, 1323

SHIPS AND BOATS, including their fittings—1289, 1303, 1315

STEAM ENGINES—1291, 1316, 1324, 1326, 1330

WARFARE—921

---

921 J. MACKINTOSH, North Bank, Regent's Park. *Working guns.* Dated March 27, 1869.

The object of this invention is to obtain protection when working guns, and the invention consists in mounting guns on hinges or jointed frames connected with springs which balance the gun, so that when the gun is fired it recoils to a lower position, taking with it the frame for loading, and is retained by a stop which, when removed, the action of the springs brings up the gun to its firing position.—Patent completed.

1261 J. THOMPSON, Great Nelson-street, Liverpool. *Motive power.* Dated April 24, 1869.

This consists in a machine composed of an endless chain of vessels rising in water on the one side and falling in air on the other side, thus producing the revolutions of the wheels or shafts.—Patent abandoned.

1262 H. REED, Edgbaston. *Distending bags.* Dated April 24, 1869.

When it is desired to expand the bag, the closed end of the latter should be placed downwards in a tube, the open end stretched over the open or uncovered end of the tube, when, by exhausting the air or creating a sufficient vacuum therein, the bag is distended.—Patent abandoned.

1263 A. MUIR, Manchester. *Stocks and dies.* Dated April 24, 1869.

The inventor makes the stocks with rectangular projections, between which the dies fit, and he makes the screw for regulating the position of the movable die to screw into a swivel block jointed to the stocks. When this block is raised, the dies can be taken out, and when down, the head of the regulating screw holds the movable die in its place.—Patent completed.

1264 WEIGEL BROTHERS, City-road. *Shirt studs.* Dated April 24, 1869.

The stud or solitaire as the case may be consists of two parts, or, in other words, the head is movable. To the bottom plate is soldered a small hollow, oval-shaped tube, having a sort of club-shaped opening for the reception of a pin soldered to the head plate; this pin is provided with two small projections, and forms the key by which the upper and lower plates are connected.—Patent abandoned.

1265 R. FOSTER, Liscard. *Crushing and pulverising.* Dated April 24, 1869.

This consists in machinery for crushing or reducing the mineral or other substance to coarse powder. This consists in the employment of edge runners and a pan, or of plain, fluted, or roughened rolls, or of a roll and stationary plate, or of stampers, or of sneezers, or of any one or more of these, of any convenient construction, working in combination or in a conjoined operation with novel mechanism, which also forms a portion of the invention. The substance or material to be ground may be supplied to the crushing mechanism either in a dry or wet state.—Patent completed.

1266 J. HEAD, Axminster. *Harrows.* Dated April 24, 1869.

This consists in forming at the upper end of the tine or harrow a mortice joint, into which a flat bar of iron or other suitable material is tightly fitted and secured, the rein by a bolt and nut, this bolt passing through both the mortice and the bar.—Patent abandoned.

1267 S. BROOKE, Brighouse. *Carding wool.* Dated April 24, 1869.

This consists, first, in the employment of a doffer clothed either with card, filleting, or parallel rings as heretofore, also of an ordinary card stripper to work in contact with the doffer; and to the under angle formed by the said doffer and stripper the inventor applies a roller on which are a series of circular knives or flanges fixed at suitable distances apart according to the required width of the strips to be performed.—Patent abandoned.

1268 J. CRABTREE, Sheffield. *Cutting shives or bungs.* Dated April 24, 1869.

This consists in the application and employment of one or more slides, moving in a groove of a V or other suitable shape cut in the front part of the spindle of an ordinary turning or other lathe, or in a front piece screwing on or otherwise attached to such spindle.—Patent completed.

1269 C. D. ABEL, Southampton-buildings. *Velocipedes* (A communication.) Dated April 24, 1869.

The invention consists in placing upon the axle of the hand wheel as a fulcrum a double ended forked or double lever. The two ends or prongs on one side of the fulcrum of this lever pass down in a slanting direction beyond the circumference of the hind wheel where they are connected by a transverse bar, and are furthermore provided with small rollers.—Patent abandoned.

1270 P. JENSEN, Finsbury-square. *Sewing machines.* (A communication.) Dated April 24, 1869.

This consists in the peculiar construction of the spoolhook. The Wheeler and Wilson spoolhook is of a shape similar to a crescent, and the needle passes close behind it, and is then, to some extent, guided by it during part of its rotary travel. But while the open part between the two horns of the spoolhook passes the needle, the latter is not guided by it as now made. That part of the inner circumference of the spoolhook which guides the lower part of the needle just before the latter approaches, the next following projecting horn of the spoolhook is extended or prolonged so as to afford the desired guide for the needle, and prevent its catching against the spoolhook or scratching the bobbin or spool.—Patent completed.

1271 D. A. S. MACKINTOSH, Glasgow. *Cask spile.* Dated April 24, 1869.

This consists of a chamber or vessel in which two tubes are fixed. The chamber is formed with closed ends, and in each end an opening is made. Into the opening at the lower end of the chamber a tube is inserted, being soldered or otherwise fixed therein. The part of the tube which is situated inside the chamber extends upwards to very nearly the top of the chamber, and the portion of the tube which is situated outside the chamber is that by which the improved spile is fixed into the cask. In the upper end of the chamber a hole is formed, and to it a tube is connected, the tube extending to very nearly the bottom of the chamber.—Patent abandoned.

1272 A. JACK, Maybole, Ayrshire. *Reaping machines.* Dated April 24, 1869.

This consists in so arranging the joints or couplings between the main frame of the machine and finger-bar that they are concentric with the crank or longitudinal shaft, being attached thereto by eyes or bearings which surround the crank shaft.—Patent completed.

1273 A. CLARK, Chancery-lane. *Reaping and mowing machines.* (A communication.) Dated April 24, 1869.

The invention consists in making the finger-bar, that is to say, the bar to which the fingers are secured, of one single piece, and in extending it in an elevated position backward along the inner side of the driving wheel, so that it will support the box in which the driving wheel has its bearings, and also the pole and all the other mechanism connected with the driving of the cutting and raking apparatus and reel.—Patent abandoned.

1274 J. CUDBIRD, Hingham. *Motive power.* Dated April 24, 1869.

This consists in employing a circular rotating lever in combination with wheel work in the construction of machinery for obtaining motive power. This circular rotating lever operates upon the same principle as the lever of the first order (a poker, for instance), with this difference the poker has a vibratory or up and down motion imparted to it, whereas the lever employed, instead of being formed of a straight bar or rod of iron, is formed as a wheel with a circular rim.—Patent completed.

1275 O. ENGHOLM, Edinburgh. *Preservation of food.*

This consists in the simple process of stirring or mixing and spreading semi-liquid substances, such as the whites and yolks of eggs, either separately or combined, in thin layers over surfaces such as plates of metal, glass, porcelain, wood, or other non-injurious substance which would not be chemically acted upon by the matters, and there and then subjected to or acted upon by a current or blast of pure and dry air, or otherwise air heated to such a low temperature as would carry off all the watery matter or moisture, and useless or unimportant volatile odours or gases given off therewith, so as thereby to thoroughly dry or desiccate the useful solid matters in a granular state.—Patent completed.

1276 O. ENGHOLM, Edinburgh. *Preserving food.* Dated April 24, 1869.

This consists in drawing the salt water from a closed cistern, or from tanks in which the fish are being transported, and forcing it through a pipe or pipes, or it may be a close chamber with a set of pipes leading from it, through which the water is forced; the other end or ends of such conducting or inducing pipes convey the water into the same or other cisterns again, by preference down through the lid into the body of water.—Patent abandoned.

1277 J. SCHARR, Leith. *Liquid soaps.* Dated April 24, 1869.

The mixtures are as follows:—No. 1. Wheat bran, 6lb.; linseed, 58lb.; caustic soda, 32lb.; potash, 80lb.; calcined soda, 95lb.; ton natron, 95lb.; glaubers salt, 25lb.; sal ammoniac, 7lb.; pitch, 57lb.; tallow, 1½lb. No. 2. Oleine, 20lb.; olive oil, 10lb.; butter, 5½lb.; rape seed oil, 5lb.; glycerine, 4lb.; turpentine, 6lb.; benzine, 1½lb.; sal ammoniac spirits, 7lb.—Patent abandoned.

1278 T. FORSTER and P. B. COW, Streatham-common. *Indiarubber compounds.* Dated April 24, 1869.

The inventors make a new compound by combining with indiarubber a substance called coorongite, and which has just been imported into this country for the first time.—Patent completed.

1279 W. R. LAKE, Chancery-lane. *Axle boxes.* (A communication.) Dated April 24, 1869.

This consists in certain improvements in the construction of the axle boxes of railway rolling stock and other vehicles and journals for the purpose of obtaining a constant and uniform supply of lubricating material where required. This purpose is accomplished by the admission of air into an airtight vessel or chamber containing the lubricating fluid in connection with the axle box or journal, at such times, and to such an extent, as to permit a sufficient quantity of the lubricating fluid to flow into the desired position.—Patent completed.

1280 G. WHITE, Cheapside. *Carding tow.* (A communication.) Dated April 26, 1869.

One of the principal features of this apparatus consists in the size of the main carding roller, which in this apparatus replaces the large carding drum hitherto made use of in low carding engines, and which main carding roller in this improved apparatus is of a much smaller diameter than the carding drum of ordinary low carding engines. Another important part of the invention consists in the use of two pairs of feed rollers which deliver the material to the main carding roller and at the same time act as drawing or stretching rollers on the tow, before this latter reaches the said main carding roller.—Patent completed.

1281 L. FARREL and W. TURNER, Dublin. *Velocipedes* Dated April 26, 1869.

This consists in the utilisation of the weight of the body to be thrown alternately upon a saddle or seat bar, and upon a footboard to be supplied for the purpose as a substitute for the muscular action of the legs on a crank as at present performed. Also in attaching a T-shaped rod or bar to a saddle or seat bar or to a lever handle, or to both, so that when the lever handle is pressed down it may act on the top of the T-shaped bar, which being connected with the saddle bar or lever handle causes or assists in causing the cranked axle of the machine attached to the saddle bar to revolve; and in applying a brake by means of a bar of metal attached to the outer end of the lever handle of the guide wheel.—Patent completed.

1282 A. WATSON, Newington Green-road. *Sleeve links* Dated April 26, 1869.

The inventor employs a front plate, to which a bar or back plate is pivoted or pin jointed so as to turn around such pivot or pin joint in a plane parallel, or nearly so, to the plane of the front plate. This bar or back plate has a stud or studs projecting therefrom to enter a recess or recesses formed in the back of the front plate, or, if desired, such recesses may be dispensed with, in which case the pivot or pin joint will be made to work somewhat stiffly.—Patent abandoned.

1283 J. CUNNINGHAM, Harpford. *Bread slicer.* Dated April 26, 1869.

This consists in constructing a square or any other suitably shaped box, case, or trunk, either of wood or metal, with a screw or racks and pinions, and a thrust operated or worked by cams or spur gear and screws, giving the necessary feed for the thickness of bread or meat required. Attached to the side of the box, case, or trunk is a horizontal shaft fitted with a revolving knife at either end, which is worked by a handle or by the foot by means of a treadle, thus leaving the hands free to pick up with a fork or otherwise the bread and meat, which are cut in slices and placed in separate compartments.—Patent abandoned.

1824 H. HALL, Burton-on-Trent. *Motive power.* Dated April 26, 1869.

This consists in the employment of rollers comprising wheels, drums, or cylinders carrying some flexible material, one of which being caused to revolve presses against another and imparts rotary motion thereto, and so on for as many wheels or rollers as are required to be driven. The rollers are made, by preference, with flanges, so that the flexible material may be effectually retained on the surface or surfaces, but they are also made without flanges.—Patent completed.

1285 This application is still under the consideration of the Attorney General.

1286 J. SMITH, Dublin. *Railway signals.* Dated April 26, 1869.

The inventor proposes to construct on any line of railway an insulated conductor broken or interrupted in such lengths as may seem most suitable, such conductor being connected, by means of metallic rollers or other convenient arrangement, with one of the poles of a battery attached to the train, the other pole of such battery being connected electrically with the earth.—Patent completed.

1287 A. V. NEWTON, Chancery-lane. *Parasol.* (A communication.) Dated April 26, 1869.

This consists in so arranging the ribs, the stretchers, and the cover of parasols, that when in the spread or expanded condition, the ribs will project at right angles to the stalk, forming for the most part a flat top with a central conical extension on one side of the top to be capable of adjustment on the stalk, so that the conical extension may project above or below the flat part of the top or parachute formed by the projecting ribs.—Patent completed.

1288 W. E. NEWTON, Chancery-lane. *Steam generators* (A communication.) Dated April 26, 1869.

This consists in constructing a steam generator or condenser of main and branch pipes or pipe, like structures arranged to occupy right-angled or cross positions, and forming tiers and rows of tubes connected so as to form but a single structure yet independent as regards separate expansion and contraction, and allowing of free circulation between or around as well as through them in various directions.—Patent completed.

1289 R. STERNE, Cork. *Anchors.* Dated April 26, 1869

The stock is constructed in a curved or crescent form and is made heavy at the centre in order to give the anchor unstable equilibrium when it is dropped in the wrong position. When the point of the stock rests on and bites the ground in that position, it becomes a power lever which cants the anchor over immediately any strain is brought on the cable, and thereby causes one of the flukes to bite or enter the ground.—Patent completed.

1290 S. OAKMAN, Boston, U.S.A. *Furnaces.* Dated April 21, 1869.

This consists in combining with a smelting or other furnace a vacuum chamber, in which the exhaust is produced by mechanical means, the chamber being connected to the furnace by suitable flues so that a proper draft may be maintained. This vacuum chamber has inlets over

the ports of the furnace so that the flame and heated products of combustion coming from the ports may be drawn into the vacuum chamber, and thus away from the workman.—Patent completed.

1291 G. HAWXHURST and J. POLLOCK, San Francisco. *Preventing corrosion in boilers.* Dated April 26, 1869.

This consists in mingling with the distilled water within the boiler, or upon its way thereto, a strong solution of caustic lime in such quantity and at such intervals of time that the water contained in the boiler will be a weak solution of the same.—Patent completed.

1292 W. PROWETT, Southwark. *Knitting machines.* Dated April 26, 1869.

In constructing a knitting machine the inventor employs bearded needles similar, or nearly so, to ordinary hosiery needles, and he mounts them on slides which are actuated in such a manner as to give to the needles an endway traverse. The slides are arranged side by side in suitable guides. Their number depends on the width of the work the machine is required to make, and on the gauge of the machine. The slides are worked by cams, which act upon them in succession and progressively from side to side of the machine. Each pair of needles, as its slide is drawn back, passes under a stationary bar, called the presser bar, which, by bearing on the boards, closes them down to the stems. Beyond the presser bar is another stationary bar having teeth upon it, and the needles pass between the teeth. This bar the inventor calls the comb bar. The heads of the needles, when they have passed behind the presser bar, enter between the teeth of the comb bar. —Patent completed.

1293 W. R. LAKE, Chancery-lane. *Locks.* (A communication.) Dated April 27, 1869.

This relates to locks provided with a set of circular plates or tumblers, which, by their position in relation to each other and to certain parts of the mechanism, prevent or permit the actuation of the lock by a handle or knob outside the door wherein the lock is placed, and which handle furnishes the only means of communication with the interior of the lock from the outside of the door, the lock having no keyhole or other aperture through which such communication could be effected. The handle is connected to the tumblers by a spindle, and is furnished with a graduated scale, the position of whose numbers in relation to a fixed point or points on the lock case form the only means for ascertaining in what manner the lock must be manipulated to allow the door to be opened. —Patent completed.

1294 J. P. COOPER, Bow, E. *Nuts and bolts.* Dated April 27, 1869.

This consists in forming a recess in the face or other part of the nut, and in fitting a rail in the recess. The bolt is made with a series of grooves or channels for the entire length of its threaded portion, into one or other of which grooves the pawl is caused to take. A spring or other appliance may be employed to act upon the pawl. —Patent abandoned.

1295 B. DOBSON, Bolton. *Carding engines.* (A communication.) Dated April 27, 1869.

The radial arms and cam wheels are made as usual, and discs with projections and recesses on their circumferences are employed to govern the order of succession in which the top flats are lifted. The slides are made in two parts, and to the upper part of one of each of them is jointed a weighted elbow lever, the lower end of which forms a catch.—Patent completed.

1296 R. FLOWER and M. CROWLEY, Durrow, Ireland. *Organs.* Dated April 27, 1869.

This consists in the construction of an instrument containing but one row of keys capable of detaching the ordinary lever board, so as to act on a single or double set of palets at pleasure, and thereby instantly producing on this one row of keys the effect of two or three. In organs of the ordinary construction, the lever boards are made in one piece and are fixtures, but, according to this invention, the lever boards are divided, one being a fixture and the other movable.—Patent completed.

1297 J. CANE, Kew. *Fusee cases.* Dated April 27, 1869.

This consists of a tube made by preference of metal. In the interior is a bed or cup free to slide therein, motion being imparted to it by a stud attached to a pin connected to the cup free to travel in a slot in the case.—Patent abandoned.

1298 J. H. SAMS, Aberdeen. *Sewing machines.* Dated April 27, 1869.

The inventor uses a circular disc, thick at the centre, and tapering to the edges. This disc is pierced obliquely through its centre, and then keyed on or otherwise fastened to a rod or shaft, which is driven by suitable gearing from the hand wheel of the seed-sowing machine, so that the plane of the disc is inclined at any required angle to the shaft. The disc is arranged to work on a flat or round-bottom hopper, and, in its alternating right and left motion, in each revolution sweeps the grain or seed over the discharge hole, through which it falls into the pipes.—Patent completed.

1299 J. ANDERSON, Londonderry. *Velocipedes.* Dated April 27, 1869.

In one modification with two wheels, the front wheel is arranged in a swivel for steering and for supporting the front end of the reach or frame, whilst the propelling action is applied to the hind wheel, the axle of which is formed with two cranks having their pins in line and not on opposite sides of the axis. The cranks are acted upon by connecting rods jointed to the arms of a propelling lever, centred upon the reach at a point near the front of the hind wheel. The propelling lever has arms projecting forward, to which stirrups are suspended for the feet, and a handle is carried up from it in front to be taken hold of and have the action of the arms applied to it. The saddle or seat is hinged or otherwise connected to the frame so that it can oscillate vertically, and it is connected to the propelling lever behind the fulcrum of the latter so as to communicate the action thereto.—Patent abandoned.

1300 R. MARSHALL, Burnley. *Wheels.* Dated April 27, 1869.

This consists in a novel and peculiar combination of a metallic nave or boss with spokes or arms of wood and a felloe or rim either of the ordinary construction or of a single piece of wood bent in the form of a circle and surrounded by an iron hoop or tyre.—Patent abandoned.

1301 H. W. HART, Fitzroy-road, W. *Ovens.* Dated April 27, 1869.

This consists in constructing ovens of a closed metal chamber provided with a door or doors at one or both ends or sides, such door being by preference made of sufficient width to allow of a table or false bottom to the oven being drawn in and out through the same. This chamber is surrounded by a metal casing so constructed as to leave a space between it and the chamber on every side, in which space is contained water.—Patent abandoned.

1302 T. ASPDEN and E. H. LAMBERT, Leeds. *Boots and shoes.* Dated April 27, 1869.

The inventor fixes between the "insole" and the out sole of the boot or shoe an air tube or channel. This tube passes longitudinally through the heel and the "waist" of the boot or shoe, and has at its upper side a longitudinal slot or opening. A series of holes is formed in that part of the "insole" which is over the opening in the air tube, and air enters the tube at the heel end thereof and passes up into the boot or shoe through the said opening and holes.—Patent abandoned.

1303 J. H. SIMPSON, Bolton-street, Piccadilly. *Propelling by currents of air.* Dated April 27, 1869.

Hitherto the pneumatic emotive power for pneumatic propulsion has been obtained only by putting a certain volume of atmospheric air into motion by means of a pump, fan, jet, or otherwise, regardless of density incidental thereto. The inventor proposes to utilise the contracting and expansion of air due to forced changes of temperature in conjunction with fans, pumps, blowers, or already applied means of putting the air into motion in order to obtain an increased effect and a quicker transit of trains or supply of air for ventilation without having to increase the dimension or the validity of the blowing machine.—Patent abandoned.

1304 O. MOSELEY, Covent Garden. *Smoking pipes.* Dated April 27, 1869.

The inventor constructs an outer case of wood earthy or other suitable material or compound, in which he inserts the true bowl of the pipe, and, although the external or false case may be of any ordinary form, it is preferred to make it spherical or globular, and to colour it in imitation of a billiard ball; it is bored through for the insertion of the true bowl and for the application of a cylinder of chalk beneath the bowl.—Patent completed.

1305 T. A. HABERKORN and B. RUDOLPH, Berlin. *Sewing machines.* Dated April 28, 1869.

The main shaft is put in motion by means of the handle and the flywheel, either by hand or treadle in the ordinary manner. The working of the machine is effected by the eccentrics set on the main shaft in the following manner:—The leading or feed rod is set in reciprocating motion by the eccentric upon which it is fixed. The former then acts upon the leading prism or feed cylinder joined to it by one end, and this again transfers its movement to the needle bar, so that the latter is obliged to perform with the needle applied to it an alternating horizontal motion. The eccentrics actuate the two alternating levers in such a way that one of them rises whilst the other descends.—Patent completed.

1306 I. J. J. LEWIS, Manchester. *Hat ventilating.* Dated April 28, 1869.

This consists principally in applying the system of a single shaft or tube divided by a partition or "brattice" into upcast and downcast shafts (such as is frequently used for ventilating mines) to the ventilation of hats or other coverings for the head.—Patent abandoned.

1307 J. B. KROLL and A. FROMENT, Paris. *Percolators.* Dated April 28, 1869.

This consists, first, in having the bottom of the upper cylinder solid, with a central aperture or valve worked by a key from the outside; second, in adapting a tap thereto; third, in the employment of an inner recipient or smaller cylinder (which is placed in the interior of the first named one), at the bottom of which the filter is fixed, and below and round it a number of circular openings are made for the passage of the filtered liquid.—Patent abandoned.

1308 G. HEYES, Radcliffe, and E. BARLOW, Little Leven, Lancashire. *Winding yarn.* Dated April 28, 1869.

This consists in improved arrangements of mechanism for enabling the yarns to be wound on the bobbin or pirns at a uniform speed, and placed regularly side by side. The spindles of the bobbins are driven by bands on the tin drum in the usual manner, but, instead of giving the drum a uniform speed as at present, it is given a continually varying speed, according to the varying diameters of the parts of the bobbin where the yarn is received, and the heart wheel for working the traversing guides has a varying speed, corresponding with that of the tin drum.—Patent completed.

1309 N. VOICE, Handcross, Sussex. *Cask tilts.* Dated April 28, 1869.

This consists in the employment of a tube, band, or length of indiarubber or other suitable elastic material suspended between two points across the back part of the stand. When a full cask is placed upon the stand its back end bears upon the indiarubber and forces it down upon a curved bar below, but as the weight of the cask and contents becomes gradually lighter as the contents are drawn off, the indiarubber is able to gradually overcome the weight and to resume its normal position, thereby gradually lifting the back end of the cask.—Patent abandoned.

1310 H. A. BONNEVILLE, Paris. *Concentrating caloric.* Dated April 28, 1869.

This consists in concentrating the degree of heat which is deemed sufficient and in preventing the radiation and loss of the caloric contained by the water poured into vessels, such as baths, intended to hold warm water by enclosing them in an envelope or covering made of felt, or felted stuff, or any other material enjoying the property of preventing the radiation of heat.—Patent completed.

1311 J. PIM, Finsbury Circus. *Ventilating.* Dated April 28, 1869.

The apparatus is preferably made somewhat in the form of an umbrella, in order that it may be expanded and raised to the upper part of the apartment and be moved about therein, whereby the vitiated air in the upper part of the chamber becomes broken up and dispersed, fresh air at the same time taking its place.—Patent abandoned.

1312 L. ISAAC, Tottenham. *Folding table.* Dated April 28, 1869.

This invention is designed to enable tables, stands, or stools to be closed up within a small compass so as to occupy very little room when not required for use, and in some cases so that the the top and base framing of a small table or stool can be packed up within a tube which then serves as a walking stick (made to carry an umbrella if desired), arranged in such a manner that when the parts are opened out and placed in position, the tube or a part of it shall serve as the leg of the table, stand, or stool. —Patent completed.

1313 E. COOPER, Laurence Pountney-lane. *Ventilating hats.* Dated April 28, 1869.

This consists in adapting to the inside of hats, and by preference at that part thereof where the head lining is situated, a piece of cork or other suitable waterproof material or fabric, so made as to leave a series of vertical or diagonal channels or passages for the admission of cold air and emission of perspiration or heated air from the inside of the hat when placed on the head of the wearer thereof.—Patent completed.

1314 T. BOSTOCK, Stone, Staffordshire. *Elastic shoes.* Dated April 28, 1869.

This consists in the application of the elastic fabric or spring beneath the same portion of the upper, so that it is wholly or partially concealed, and will yet have sufficient play or action as to allow of the boot or shoe being readily put on or taken off the foot.—Patent completed.

1315 R. B. FORBES, Boston, U.S.A. *Rigging vessels.* Dated April 28, 1869.

This consists, first, in bending the sails by battens, jack stays, or other convenient and usual attachments to the yards at their foot instead of to those at the head of the sails, thus rendering the largest and longest side of the sail, which is most difficult to subdue or furl in strong breezes, permanently and constantly furled or subdued. Second, the yards above the lower yard, excepting sky sails, are slung and parallel or secured so as to brace very sharp and above the eyes of the standing rigging and back stays, and they do not hoist and lower but are permanent. The lower yard is as usual permanent, but is also slung just above the eyes of the rigging.—Patent completed.

1316 J. FROLICH, Barnes. *Gas generators.* Dated April 28, 1869.

This consists of two firebrick chambers connected at the bottoms by a short flue. The first chamber contains the fuel in a powdered state, such as small coal, coal dust, saw dust, or peat, and must be fed from time to time at the top. The fuel descends by gravity, and is burnt by the aid of fan blast entering through a number of tuyeres near the bottom of the chamber. The gaseous products of this combustion pass through the flue into the second chamber, which is supplied from time to time by a door placed at or near the top with coke or large pieces of non-bituminous coal, so that all the gases resulting from the combustion in the first chamber are forced to ascend through a column of red hot coke. The gas is thus converted into carbonic oxide, and is then ready for use, and the carbonic oxide gas thus produced may be burnt by either hot or cold blast, as the process to be carried out requires a higher or lower degree of heat.—Patent completed.

1317 A. MEREDITH, Newgate-street. *Iron and steel.* Dated April 28, 1869.

The inventor raises the temperature of the iron to a very high degree before beginning to force the blast through it by means of a refinery fire in the usual way of making refined iron. In this preliminary process the impurities are in part separated, whilst at the same time the metal is raised to the heat necessary for the successful action of the blast passing through it. When the metal is at the highest heat attainable in the refinery the metal is at once run into the Bessemer vessel and treated by the Bessemer process, which is conducted in the usual way and regulated according to the appearance of the flame, as is well understood. In carrying this invention into effect the iron may advantageously be run directly from the blast furnace into the refinery furnace.—Patent completed.

1318 D. GREIG, R. BURTON, J. GOZNEY, and T. ATKINSON, Leeds. *Cultivating land.* Dated April 28, 1869.

The first part of this invention relates to improvements in the construction of cultivating implements to facilitate twining at the ends of the louts. When giving motion to cultivating implements by means of hauling ropes actuated by a stationary engine or engines, the inventors connect the hauling ropes to a bar or lever mounted on the implement so that the point of draught shall be behind the centre of the steerage wheel. When the direction of draught is changed the bar or lever to which the hauling ropes are connected swings round, passing over the top of the steerage, and after swinging past a certain point it acts on the steerage wheel and directs it so as to assist in turning the implement.—Patent completed.

1319 W. E. GEDGE, Wellington-street, W.C. *Stringed instruments.* (A communication.) Dated April 28, 1869.

The object sought is the rigidity of and the maintenance of an invariable distance between the head bar or pin plate, in which are fixed the ends of the pins and the lower bar; and the construction of this new system of barring or framing is intended, in the first place, to oppose any drawing together of these two parts by the interposition of rigid metallic bars of any shape, flat, square, or T-shaped, and even of hollow iron; and, in the second place, to prevent the head bar or pin plate from being drawn by the traction of the strings from its primitive vertical position, and inclining towards the action of the strings. These objects are attained by the use of an arrangement of cramps applied in the face opposite that on which the strings are placed.—Patent abandoned.

1320 H. BRAY and H. ADAMS, Nottingham. *Graining in oils.* Dated April 28, 1869.

A composition of glue and treacle, or other agents or equivalents, is prepared and placed in a mould, upon which the inventor places a board or other covering which fits within the mould. They then press this board or other covering on the composition within the mould, which he next uncovers, and removes the composition. They then employ soap and soda with raw linseed oil and vegetable lampblack or other equivalents or agents, and boil them together over a fire or heated surface until the water therein has evaporated.—Patent abandoned.

1321 W. R. LAKE, Chancery-lane. *Generating steam.* Dated April 28, 1869.

This relates to a furnace which may be used in a steam generator, or for many other analogous purposes, and it

consists in placing within the firebox of such furnace a chamber opening above the grate bars through which the coal is fed, which coal, before falling upon the grate bars, is exposed to the action of the heat evolved within the firebox while retained in the chamber, above which is a cover for preventing the escape of the gases distilled from the coal, which may be utilised either by bringing them down in a pipe or pipes and discharging them below the incandescent coke through which they will pass, or they may be conducted away in pipes to be utilised in another place.—Patent completed.

1322 M. WILKIN, Paddington, and J. CLARK, South-street, Finsbury. *Radiating axles.* Dated April 29, 1869.
The inventors construct the carriage longer and lighter than usual, and mount it upon six wheels instead of four. The several pairs of wheels are fitted to bogie frames, which have movement under the framing of the carriage, the centre pair having lateral movement to the extent of the versed sine of the curve, and the fore and aft pairs, which are fitted with central fulcrum pins, move or radiate round them so that the line of the axles, if produced, meets in the centre of the curve. The bogie fitted to the centre pair of wheels is furnished with an elongated pole extending on each side to half the wheel base, and the fore and aft bogies are furnished with corresponding poles on the inside to meet the aforesaid pole.—Patent abandoned.

1323 R. GRIFFITH, Aberdeen Park-road, N. *Bicycles.* Dated April 29, 1869.
This consists in applying and attaching outside each of the usual pieces of elastic or side springs a protective piece of kid leather or other suitable material, according to the nature and strength of the boot or shoe.—Patent abandoned.

1324 O. ROSE, Bolton. *Steam engines.* Dated April 29, 1869.
These improvements consists in using a small steam piston and cylinder which may be combined with what is termed a "dash pot" for suddenly closing each emission valve, or for suddenly opening each emission valve when so arranged that the steam can be admitted and exhausted from the small cylinder through ports in its piston and cylinder at each movement thereof.—Patent completed.

1325 J. G. F. and G. W. BLOW, Commercial-street. *Driving bands.* Dated April 29, 1869.
The inventors employ thin and flexible steel bands on which they thread small pieces of leather of a width equal to the thickness of the band which it is desired to make. The strips of leather run transversely across the driving band, so that the length of the strip corresponds with the width of the band.—Patent abandoned.

1326 E. CROWE, Middlesbrough-on-Tees. *Utilising waste heat.* Dated April 29, 1869.
The inventor employs a boiler of two horizontal tubes arranged one over the other, and connected by a number of upright tubes arranged at short distances apart along the horizontal tubes. The water line of the boiler is at the diameter of the upper tube or thereabouts, and the boiler below this line is enclosed in a chamber of brickwork into which at one end the products from the furnace enter, and which at the other end is connected with the chimney, so that the chamber is in fact the flue of the furnace. The sides of the chamber at the level of the vertical tubes are corrugated so as alternately to approach and recede from the vertical tubes, so that the draught is caused to pass in an undulating direction. This causes it to impinge more effectually on the vertical pipes, and at the same time sufficient space is obtained for a man to pass through the chamber to clean it from time to time.—Patent completed.

1327 R. ELSDON, Brockham, Surrey. *Limekilns.* Dated April 30, 1869.
The furnace is built at one end or foot of kiln for combustion of coal or other fuel, and beyond this is a second furnace, in which coke or other suitable fuel is burnt. The gases from the first pass over, and are brought into immediate contact with the heated fuel in the second furnace, and are there mixed with a larger quantity of atmospheric air than is necessary for perfect combustion of the fuel. The total product of combustion and distillation from the coke furnace passes through a brick chamber, where a still further supply of air is introduced sufficient to reduce the temperature to the degree required. —Patent completed.

1328 W. SPENCE, Chancery-lane. *Making felt.* (A communication.) Dated April 30, 1869.
According to this invention in machines for making felt in sheets, the table which covers the wool to be felted has imparted to it at the same time both a longitudinal and a transverse reciprocating motion. The table is thus caused to work both longitudinally and transversely at the same time, but with the extent of its motion in one direction differing from the extent of its motion in the other direction.—Patent completed.

1329 J. BROADFOOT, Glasgow. *Lavatories.* Dated April 30, 1869.
This consists in forming a hollow support or stand for the lavatory top or basin piece, into which the used water may be allowed to pass through a plug-hole in the bottom of the basin, and which is fitted with a tap at the bottom for withdrawing such used water periodically. The basin piece may be of earthenware or enamelled cast iron, and the support may be of cast iron, zinc, or other metal, or of earthenware. The support is made in the form of an ornamental bracket, and is fixed against the bulk-head, partition, or lining by screws, some of which can be entered from the inside, whilst lugs may be formed on the hollow support for others.—Patent completed.

1330 J. JAMIESON, Oldham, and T. HOLT, Rochdale. *Steam engines.* Dated April 30, 1869.
The inventors employ four valves having a steam valve and an exhaust valve at each end of the cylinder, each working independently on the facing of its respective port, the valves being of a plate form, and the exhaust ports and their valves being of about twice the area of the steam ports and their valves.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated November 9, 1869.

3220 J. V. Michaux, Hampstead. An improved method or means of securing corks in bottles.

3221 S. Heath, Walsall, Staffordshire. An improved machine or apparatus for clipping horses.

3222 R. Aders, Manchester. Improvements in the tinning of metals.

3223 R. Jones, Birmingham. A special and general paper, card, or form holder, such as for address cards, envelopes, bill heads, and general stationery, or like matter, and which said invention is also applicable for holding special patterns or fancy goods not of a bulky character.

3224 A. C. Kirk, Glasgow. Improvements in or connected with retorts.

3225 G. D. Davis, Woodstock-road, East India-road. Improvements in machinery for working rudders.

3226 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machines for heckling hemp.

3227 T. Hattersley, Leeds. Improvements in spindles and flyers used in the spinning and preparing of flax, tow, hemp, jute, worsted, wool, cotton, silk, and other fibrous substances.

3228 C. Mole, Tottenham Court-road. Improvements in the manufacture of boots and shoes.

3229 A. M. Clark, Chancery-lane. Improvements in the transportation of letters, parcels, and other freight by atmospheric pressure, and in apparatus connected therewith.

Dated November 10, 1869.

3230 J. and H. Tracy, Shacklewell-lane, Dalston. An improved stick or stem for umbrellas, parasols, whip and other handles.

3231 A. Bohlken, Varel, Oldenburg. Improvements in terriers.

3232 E. Thomas, Cardiff-street, Aberdare, Glamorganshire. An improvement in the construction of miners' safety lamps.

3233 W. Donbavand, Manchester. Improvements in balances for weighing.

3234 J. Riley, Shoreditch. Improvements in roofs and other parts of buildings.

3235 G. Knighton, Riddings, Alfreton, Derbyshire. Improvements in core barrels for making pipes and hollow castings.

3236 F. Jenkin, Fittis-row, Edinburgh. Improvements in submarine telegraph cables.

3237 J. W. Hackworth, Darlington, Durham. Improvements in slide valves for steam engines.

3238 J. Ingletop, Glasgow. Improvements in water-closets.

3239 H. Lee, Manchester. Improvements in looms for weaving.

3240 F. B. Dœring, Victoria-street, Westminster. An improved construction of stand or carriage for rock boring or excavating machines.

3241 I. and G. Battinson, Halifax, and T. and H. W. Whitehead, Leeds. Improvements in machinery for combing wool, cotton, flax, and other fibrous substances.

Dated November 11, 1869.

3242 J. Logan and W. Gardner, Paisley, Renfrewshire. An improved mode of ornamenting textile fabrics.

3343 A. Mosley, Old Radford, Nottinghamshire. Improvements in lace machinery.

3244 H. Robinson, Skipton, Yorkshire. Improvements in the construction of kilns for burning limestone, chalk, cement, or for calcining ores, part of which being applicable to blast furnaces.

3245 T. Herbert and J. C. Fowler, Leicester. Improvements in means or apparatus for signalling between various parts of a railway train.

3246 M. Tuthill, Mota Borrisokane, Tipperary. Improvements in horse gear.

3247 J. P. Budd, Ystalyfera, near Swansea, Glamorganshire. Improvements in the manufacture of iron.

3248 J. M'Cormick, Boston, Massachusetts, U.S.A. An improvement in the process of brewing malt and other substances.

3249 I. Nasch, Berlin, Prussia. Improvements in button-hole sewing machines.

3250 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in combination locks.

3251 J. Guesne, Charlotte-street, Portland-road. Improvements for an organ and piano combined.

3252 G. Simpson and L. Strauss, Glasgow. Improvements in arrangements or apparatus for withdrawing beverages or other liquids from casks or other vessels, and for elevating the same.

3253 J. M. Rowan and T. R. Horton, Glasgow. Improvements in steam engines and boilers.

3254 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of caoutchouc, gutta-percha, and analogous gums for the production therefrom of articles of utility and ornament.

3255 J. Mason, Birmingham. An improvement or improvements in metallic pens.

3256 W. Harris, Birmingham. Improvements in locks and latches.

3257 P. Wilson, Birmingham. Improvements in locks and latches, and in keys for locks, and in attaching door and other knobs to spindles.

3258 H. Rochatte, Boulevart de Strasbourg, Paris. Improvements in breech-loading firearms with central percussion.

3259 G. A. Buchholz, Regent's Park. Improved machinery for hulling grain.

Dated November 12, 1869.

3260 M. Benson, Southampton-buildings, Chancery-lane. Improvements in a machine for dusting bran, or separating the flour from the bran after it has undergone the usual process of bolting, and also for cleansing cracked wheat and other grain.

3261 B. Shaw, Calder Soap Works, Wakefield, Yorkshire. Improvements in machinery for cutting soap.

3262 S. Martin, Clarence Works, Sheffield. Improvements in the construction of chairs for supporting the rails of rail and tramways.

3263 C. Brakell, North Moor Foundry, Oldham. Improvements in obtaining and applying motive power.

3264 S. Chatwood and R. Kenyon, Bolton-le-Moors, Lancashire. Improvements in furnaces, and in apparatus connected therewith.

3265 O. Rose, Bolton, Lancashire. Improvements in pistons for steam and other motive engines.

3266 G. D. Edmeston, Preston, Lancashire. Improvements in hammers to be worked by steam or other elastic fluid.

3267 W. Gorman, Glasgow. Improvements in the manufacture of iron and steel, and in apparatus therefor, parts of the improvements being also applicable to furnaces of various kinds, and parts to some motive-power purposes.

3268 T. Snow, Inner Temple. An improved column for exhibiting notices at railway stations and other public places.

3269 W. E. and F. Dobson, Meadow Mill, Nottingham. Improvements in the manufacture or production of shawls made on lace machines.

3270 S. W. Shaw, Bower Hill House, Maidstone, Kent. Improvements in burning bricks.

3271 H. R. Minns, Bristol. Improvements in letter pillar posts.

Dated November 13, 1869.

3272 G. H. Hannaford, Finsbury-place South, City. Improvements in apparatus for working, locking, and controlling railway switches, points, and signals.

3273 J. Edwards, Richmond-road, Hackney. Improvements in the permanent way of railways, and for giving signals on the same.

3274 W. E. Gedge, Wellington-street, Strand. A new or improved composition or electro-cathodic insulating mastic to be used as a coating for preserving metal and other surfaces from the effects of humidity, and also as a cement.

3275 W. E. Gedge, Wellington-street, Strand. An improved machine for cutting, drilling, and shaping wood and metals.

3276 C. H. Holt, Byrom-street, St. John's, Manchester. Improvements in apparatus for obtaining blast in smelting and other furnaces, which improvements are also applicable in injecting air for other purposes.

3277 R. Hardman, Ramsbottom, Lancashire, and G. Hardman, Newchurch, Lancashire. Improvements in carding engines.

3278 C. Burgon and J. Ball, Sheffield. Improvements in the manufacture of sheep shears.

3279 R. Smith and J. Higginbottom, Paper Staining Works, Hyde-road, Manchester. Certain improvements in the manufacture of paper-hangings.

3280 C. Sutton, Holloway-road. An improved means of, and apparatus for, ascertaining the presence of certain bodies which are concealed from view, and for discriminating between one body and another.

3281 T. A. Dillon, Dublin. An improved safety lamp.

3282 W. Richardson, Oldham. Improvements applicable to valves of steam engine cylinders.

3283 H. H. Grierson and J. M. Rigby, Manchester. Improvements in machinery for cutting or dressing stone.

3284 J. Henderson, Bishopton, Renfrewshire. Improvements in treating certain ores and in obtaining products therefrom.

3285 C. D. Saintgeot and C. Poucel, Rue Ste. Appoline, Paris. Preventing and removing incrustations in steam boilers.

3286 R. Ganthony, Richmond, Surrey. An improved inking or stamping pad.

Dated November 15, 1869.

3287 P. Koch, Manchester. Improvements connected with the knobs or handles of locks and latches of doors and gates or similar purposes.

3288 W. E. Gedge, Wellington-street, Strand. A novel manufacture of box for matches and other objects.

3289 F. Clarbour and W. E. Teale, Salford, Lancashire. Certain improvements in mining lamps.

3290 F. Brampton, Birmingham. Improvements in locks.

3291 F. Clark, Tamworth, Warwickshire. Improvements in machinery for the manufacture of pipes, bricks, tiles, and other articles from clay and other materials.

3292 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved process for refining and desilvering lead, and apparatus employed for that purpose.

3293 J. Tribe, St. John-street, Smithfield, and J. Mallet, Charles-street, St. John-street-road. Improvements in despatch boxes and other similar articles.

3294 A. Jugla, Regent-street. An improvement in gloves.

3295 W. Gossage, Widnes, Lancashire. Improvements in obtaining a certain compound of soda by the decomposition of sulphate of soda, and a certain compound of potassa by the decomposition of sulphate of potassa; also in obtaining sulphur, either free or combined, from the gaseous products of such decompositions.

3296 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in means and machinery for clipping horses and other animals.

3297 G. R. Mather, Wellingborough, Northamptonshire. Improvements in means or apparatus for cutting or giving form to wood.

3298 J. G. Jones, Blaina, near Newport, Monmouthshire. Improvements in apparatus for breaking down coal.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," November 16, 1869.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE New Vade Mecum (invented and manufactured by Charles H. Vincent, optician, of 23, Windsor-street, Liverpool) consists of a telescope well adapted for tourists, &c., to which is added an excellent microscope of great power and first class definition, quite equal to others sold at ten times the price. Wonderful as it may seem, the price of this ingenious combination is only 3s. 6d., and Mr. Vincent sends it (carriage free) anywhere, with printed directions, upon receipt of post-office order or stamps to the amount of 3s. 10d.—[ADVT.]

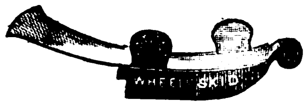
THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, NOVEMBER 26, 1869.

POUPARD *v.* FARDELL.

A CASE involving points of the greatest importance to patentees and inventors has just been argued in the Court of Chancery before Vice-Chancellor Sir R. Malins, and which occupied the court for six days. This case was briefly reported in our legal intelligence of last week, but, as it illustrates on the one hand the inevitable consequences of wrongful litigation, and on the other the importance of patentees having their inventions precisely and clearly defined, we purpose now to consider the whole case as it is presented to us by the evidence of the witnesses and the decision of the judge. The plaintiff in this case—Poupard *v.* Fardell—is the well-known weighing machine maker, of No. 7, Blackfriars-road, and is also the inventor of the serpentine screen described in these pages about twelve months since. In January, 1859, Mr. Poupard obtained letters patent for some important improvements in the construction of wheel skids, and which are embodied in what is now widely known as his curvilinear wheel skid. In order to render the subject perfectly clear we here reproduce the description of this invention as it stands in the plaintiff's specification:—"My invention consists in constructing a skid or shoe for the skidding of wheels in descending inclines with a tail-piece projecting from the back part and top of the skid chamber. This tail-piece may be carried entirely through the front of the shoe. I prefer to form it of wrought iron or steel, while the body of the shoe may be made of cast or wrought iron. I find the best results to be obtained when the projecting tail-piece is curved upwards, but I do not limit myself to so shaping it." The form of the skid is seen from the annexed cut. The history of the in-



vention is soon told, and the improvement will be easily realised by those who still use the ordinary skid. By chance, one day, the plaintiff noticed the inefficient way in which an ordinary skid acted at Blackfriars Bridge—the carter being obliged to use a whisp of straw, the object of keeping the wheel in the skid even then not being effected. On his return home the idea struck him as to how it might be obviated. The result was that he constructed the skid (for which he afterwards took out the patent), and tried it at night down all the London hills with perfect success. He then took out his patent, and his skid was supplied to between 500 and 600 omnibuses, besides other carriages.

Matters went on smoothly with respect to the skids, the plaintiff continuing their manufacture and sale until 1866, when he discovered that the defendant—Mr. Fardell, a carman in Hermitage-street, Wapping—was using similar skids for his vans. The plaintiff remonstrated with the defendant by letter, to which no answer was vouchsafed, but the result was that the use of the skids was discontinued—at least, their tails were cut off. But the partiality of the defendant for the plaintiff's skid developed itself again in 1868, when the infringement was discovered, and out of which circumstance arose the present suit. Some estimate of the importance of this cause may be formed from the fact that nearly 100 witnesses—about 60 for the plaintiff and 40 for the defendant—were examined by affidavit, and some of them in court. Amongst the plaintiff's witnesses were Colonel Phillpotts, of the Royal Horse Artillery, Quarter-master Serjeant Henderson, Wheeler-Major Green, Quarter-master Sergeant Bennett, Sergeant-Major Fairburn, Farrier-Sergeant Holt, Armourer-Sergeant Duffield, Sergeant Dovey, Sergeant Gadd, Gunner Owens, Gunner Crighton, and several artillerymen. In order to illustrate the case and present it clearly to the mind of the Vice-Chancellor—who had to act in the double capacity of judge and jury—a great number of skids, models, and actual articles used, or capable of being used, were produced in court. These may be divided into three classes—the ordinary skids used before the date of the patent, the plaintiff's patented skids, and the service skid used by the artillery for their guns. The old skids were formed flat with raised sides, a handle with an eye behind, and finishing at the other end somewhat abruptly, so as to form a sort of short trough for the wheel. Upon that there were improvements by bevelling off the corners of the raised sides, or, in their places, substituting two pairs of lugs or ears, and sloping off the substance of the floor of the skid. The service skid was very massive, also with a straight or level bottom and a large subtension of the hinder part, with an eye in it to hook on to the gun, and two pairs of lugs or ears, one pair having eyes in them. The plaintiff's skids were formed of two pieces of iron, or one of iron and one of steel, as described in his specification, with a projecting tail-piece of the upper plate, with two lugs or ears standing alternately or in pairs, and the whole chamber or course of the skid between the lugs formed a segment of a circle.

On the part of the plaintiff the evidence went to show that the invention was a new one, and its action most successful, the idea having occurred to the plaintiff as stated, and he not being able to discover from all the inquiries he had made that such a skid had ever been made or used. One of the plaintiff's witnesses, who was in the defendant's employ at the time the letter of remonstrance already referred to was sent by the plaintiff to the defendant, proved that in 1866, when the defendant was remonstrated with, by his orders the tail-pieces of the skids were cut off. After a lapse of time, however, nothing further being heard of the matter, they were resumed in the lengthened shape, by drawing out the iron if there was substance enough, or, if not, by shutting on another piece. With regard to the service skid used by the Royal Artillery, the defendant wanted to show that the tail-piece was equivalent to the continuation of metal in the plaintiff's skid. But it was clearly shown that the so-called tail-piece in the service skid was simply a massive eye-piece, which, being there only for the purpose of hanging on to the gun, was in the way and acted detrimentally. It was shown to be dangerous when used by a novice, inasmuch as if the skid was not placed before the wheel with great accuracy, the wheel might strike the eye-piece and send the skid flying. On the other hand, Colonel Phillpotts and all the other artillery witnesses stated that they considered the principle of the plaintiff's invention totally different, and highly superior to the service skid. The defendant's evidence was that the plaintiff's invention, so called, was not new, but had been known for some years antecedently to the patent, and the plaintiff's inquiries had been limited to London, it not being pretended that he had inquired either in Liverpool or Edinburgh—had he done so the result would have been probably different; that the principle of the plaintiff's and the service skid was precisely the same; that the incline was also the same when used; and that in 1854-5 the defendant had his skid altered and lengthened by a tail-piece put on the upper plate, with a curve.

The plaintiff's counsel contended that the value and novelty of the invention had been sufficiently made out, and that it had also been distinctly proved that the defendant had used skids made by his order precisely like the patented article, and that therefore the plaintiff was entitled to what he asked. The counsel for the defendant followed, insisting that the question was purely whether the invention was novel, not whether it was successful or valuable, admitting both those qualities; and it was immaterial, if it was not new, whether the plaintiff was ignorant of that fact or not. On his own specification, moreover—it was argued—the principle was the projection of the tail-piece, and the curvature and the other parts were not the principle, but only useful adjuncts; and therefore a straight skid with a straight tail-piece was as much an infringement as a curved one, and the concluding words, "this shape may be varied," threw the whole open. The curvature had been relied on; but here the specification itself denied it, and the tail-piece was the only novelty, which in fact was none. This was shown by the figures, which were merely for reference, and were valueless unless borne out by the specification. There was therefore no novelty, and the patent was bad, irrespective of the question whether the invention was a fit subject for a patent. If, said the defendant's counsel, a patent was defective as to the specification in part, it was bad entirely, and that was the case here. It had been proved that before the date of the patent the defendant had used skids in principle precisely similar to the plaintiff's. Mr. Glasse, Q.C., replied to the effect that the invention was novel and the patent valid, the specification being perfectly expressed and good.

In delivering a lengthy and elaborate judgment, the Vice-Chancellor first observed that it was a most unfortunate litigation, and one deeply to be deplored. The patent had been acquiesced in so long that it must be of great value to the plaintiff, whereas if the defendant succeeded, it would save him some £10 or £12 which the purchase of the plaintiff's skids would cost him. The Vice-Chancellor observed that there were two points raised—novelty and the sufficiency of the specification. It was sworn by one of the defendant's witnesses that thirty years ago, and therefore many years before the plaintiff's patent, he, as foreman of a manufactory, had superintended the making of skids with projecting tails for the top plate. In point of fact, that was identical in principle with the plaintiff's skid, and if that witness was to be believed there was an end of the plaintiff's case. But, from his demeanour and evidence, his Honour distrusted him, and considered that he was not to be relied upon. There was nothing to confirm his evidence, and four witnesses contradicted him. He (the Vice-Chancellor) therefore disbelieved him. Not that, perhaps, he meant to commit perjury, but, from beer or some other cause, he did not remember what happened even last week. Then, as to the field service skid, Colonel Phillpotts, Quarter master Sergeant Henderson, and others, contradicted the supposition that that skid was the same in principle with the plaintiff's. The tail was not to guide the wheel, but merely to hook up to the carriage. It was agreed by all these witnesses that it was a most inefficient one, and that accidents occurred from the tail-piece, which was an impediment instead of an advantage. Colonel Phillpotts deposed that the plaintiff's tail-piece was of great practical utility, and valuable to the public. The defendant's case, therefore, failed as to prior user by the Royal Horse Artillery.

Next, with regard to the use by the defendant himself, his Honour observed that there was a painful conflict of testimony. One set of witnesses had sworn that for years before the patent it was used by the defendant, and the other set that it was not. In this state

of things, sitting as a jury, his Honour must believe one set and disbelieve the other. What were the antecedent probabilities? The defendant was largely engaged in trade, and for many years employed skids, and in 1866 the plaintiff wrote to him on the subject of his using skids similar to the patented one. But he did not reply to that letter, and if he had then stated that since 1854 he had used them, this litigation would never perhaps have arisen. The defendant had not been cross-examined, but a great number of others for him had been, and they all deposed to the same effect—namely, that they used them. There was a body of testimony the other way, that the lower plate was always the longest, and it was impossible to reconcile the two; and on this point the defendant's case entirely failed—there had been no prior user by him. The invention was therefore novel, was admitted to be important, and was properly the subject of a patent. The plaintiff's improvement therefore being novel, important, and properly the subject of a patent, and having been acquiesced in for ten years, the question was whether the specification was sufficient.

Upon this point his Honour observed that Lord Eldon's view that the specification must be so precise as to enable a person to make the article without the drawings was no longer the law, for a specification might now consist of a figure only. Mr. Poupard's specification, with the drawings accompanying it, explained his invention with sufficient clearness to prevent the public from being misled. The words "but I do not limit myself to so shaping it" would have been better omitted, but upon none of the authorities cited, and upon no principle of justice, could he come to the conclusion that the introduction of them vitiated the patent. The plaintiff was entitled to the perpetual injunction for which he asked; to the delivery up by the defendant of all patented skids in his possession; to an account, and to an inquiry as to damages; and the defendant must pay all the costs of the suits.

Such, then, is the judgment in the present cause, and we wonder how anyone could be found so ill-advised as to persistently defend it in the face of easily ascertainable facts. The result teaches two practical lessons. The first is the folly—if nothing worse—of defending in a frivolous and vexatious manner a clear and unquestionable infringement upon the grounds of prior user, so little was really to be gained by it, and so much certainly stood the chance of being lost. Had the defendant won the cause he would only have saved himself some £2 or £3 a year for three years, as the patent expires in January, 1873. On the other hand, he stood to lose time and money to a very considerable extent, besides that loss of moral reputation which invariably follows the endeavour to deprive others of their just rights, and to persistently defend such a course of action. The second lesson inculcated by these proceedings is the necessity of inventors at all times making sure that their specifications are sufficient. This can only be effected by the employment of competent and responsible agents. The specification in the present case was prepared by Messrs. Robertson, Brooman, and Co., patent agents, of 166, Fleet-street, and was found proof against all the specious devices which could be invented to destroy its validity. It was, as the Vice-Chancellor expressed it, "sufficient." And so should all such documents be, neither redundant nor involved, neither vague nor obscure, but stating in plain and precise terms the nature of the invention, and clearly illustrating the same where necessary. "That was certainly the case here," said his Honour. Had it not been so, the defendant would most probably have gained the cause. The results would have been disastrous in the extreme to the plaintiff, besides the injustice that would have been committed in the name of the law in allowing an imitator to benefit by the brains of the legitimate inventor. As the case stands, clear evidence and an unassailable specification have given the victory to talent, industry, and inventive genius.

THE "THISTLE," THE "ROCKET," AND THE "TEAZER."

WERE we not living in the latter half of the nineteenth century, it is very probable that we should now be consulting the stars or some other equally satisfactory oracular source of information, in order to find out what evil genius or fatality was working against British gunboats. We might be inquiring whether Neptune was angry, or whether the mythical inhabitants of the vasty deep were extramischievously disposed at the present season of the year, in order to account for the unwonted series of accidents that have just befallen three of her Majesty's ships of similar build, capacity, and armament—to wit, the "Thistle," the "Rocket," and the "Teazer." The first occurrence was the calamitous boiler explosion on board the "Thistle," which has of late absorbed public attention. Next came the "Rocket," sister ship to the "Thistle." She was being taken out this day fortnight for a run over the measured mile when her boilers primed to an alarming extent. Nearly all the water was blown out of the boilers, and the fires had to be drawn, there being a very narrow escape from an explosion. To complete the series of accidents, we now have the "Teazer," a similar vessel to the other two, getting into trouble. In this case the "Teazer" was being taken from Portsmouth Harbour for the trial of her engines, preparatory to taking the place of the unfortunate "Thistle." She was placed in pilotage charge of a staff commander of the steam reserve, instead of a Queen's pilot, who is properly qualified and appointed for this service. The result was that she ran foul of the "Trafalgar," smashing a new cutter belonging to the "Teazer," and carrying away some of her mizen topmast rigging, besides carrying away the ensign, gaff, and doing other damage to the "Trafalgar," the whole amounting to at the least £50. It appears that if a proper Queen's pilot had been placed in charge the cost to the country would have been something under fifteen shillings, a very different figure of cost from that now presented. Surely discretionary powers should be given to the admiral, superintendent, or master attendant, to place in charge persons who are duly qualified for such a responsible duty, and for the protection of valuable property. Some folks — representatives of the "good old times"—hold that when one accident or fatality occurs, two more must follow, to make up the mystic list of three. We trust, now that we have completed this triangle, we shall have no more catastrophes or casualties in her Majesty's fleet.

Since the foregoing was written, another of her Majesty's ships has had a narrow escape from getting into trouble and thus completely upsetting the triangular theory of accidents above alluded to. The victim of circumstances this time was the "Druid," a wooden corvette of 10 guns, 1,322 tons, and 350-horse power nominal. She was taken on Tuesday last from Sheerness Harbour to the measured mile on the Maplin Sands, to try her engines and speed. The vessel had been tried on the Saturday previous, but was obliged to return to harbour at an early hour, in consequence of its being found impossible to retain the necessary pressure of steam, viz., 30lb. to the square inch, in the boilers, the cause being the leaking of the valves. Time was needed to remedy this defect, and the vessel accordingly remained in port until Tuesday. As far as the trial of speed and handiness of the ship went everything proved very satisfactory, although it was again found almost impossible to retain the necessary supply of steam. During the runs at full boiler power, however, the ship herself vibrated and shook fore and aft in the most unusual manner, her stern jerking with a most unpleasant lateral motion. The fore and mizen masts, from the step to the truck, also oscillated to such a degree that it seemed as though the rigging had never been made taut. After her trials the "Druid" was put under easy steam and headed for port, a fog coming on at the time. She steamed slowly for half an hour, when the leadsman announced shoal water, which was quickening. The engines were at once stopped, and the vessel backed astern, when it was found that the compasses, which were correct when the vessel left the harbour in the morning, had got out of gear, and would not travel at all. This was a decidedly uncomfortable state of things—a thickening fog, the evening closing in, the vessel out of sight of land, and out of her proper course, in shoal water. The "Otter" steam tug, however, hove in sight, and she shaped the true course of the "Druid," which vessel was then found to be about a quarter of a mile below the "Nore Light Ship," and heading seaward instead of homeward. At length the well-known black buoy was found by the "Druid's" look-out men, and, thus relieved of her difficulties, the vessel made the best of her way out of the fog and into the harbour. A court martial will probably sit on the recreant compasses and their maker, and so here endeth for the present this chapter of accidents.

PHOTOGRAPHS OF THE PLANET MARS.

MR. JOHN BROWNING, F.R.A.S., is now publishing some beautiful photographic stereograms of the planet Mars, showing its islands, seas, continents, and snow-clad poles. As the image thrown by Mars upon a photographic plate by the telescope of Mr. Warren De La Rue, F.R.S., is only about as big as a pin's head, without some explanation Mr. Browning's large, well-defined stereograms are a complete mystery, and we must confess to having been perfectly puzzled at the first sight of them. Manifestly he could not have photographed them direct from the planet, as the details were far too perfectly defined for such a mode of operating to have been employed. Obviously also the photograph was not taken from a drawing, because in the stereoscope the planet shows up with solid rotundity. A pamphlet, by Mr. R. A. Proctor, B.A., F.R.A.S., which accompanies the stereograms, solves the question.

A few years ago, Mr. Browning made a globe of Mars, and all the details were given with very great accuracy, for not a single feature was marked which had not been seen more than once, and mapped, by such keen reliable astronomical observers as Dawes, Herschel, Madler, Secchi, and Lockyer. This globe he exhibited at the Royal Astronomical Society in 1868, where it was much admired. The stereograms, therefore, are in reality photographs of Mr. Browning's globe. To get the necessary softening round the edge of the disc, Mr. Browning first tried vignetting, but as the results were unsatisfactory, the negatives were printed without vignetting, and the edges of the planet afterwards softened by hand.

Five stereograms of the planet have been taken, and all of them are good ones. Mr. Proctor's pamphlet is also handsomely printed and very interesting, as the following quotation, with which we close this brief notice, will show:—"Throughout the whole of the solar system there is no object which affords so many points of resemblance to our own earth, or exhibits so clearly the signs of

adaptation to the wants of living creatures, as the small orb which is our nearest neighbour among the exterior planets. With oceans and continents such as we have; with polar snow-caps widening in the Martial winter, and melting again under the returning sun of the Martial summer; with an atmosphere supporting clouds and mists, carrying the vapour from his seas to aggregate in snow and ice around his poles, or wafting refreshing rains over his continents; Mars presents a scene which it requires no very lively exercise of the imagination to dot with villages, towns, and cities peopled with busy workers. Over those seas—we may well believe—ride the navies of unknown nations; across those continents lie the tracks of a busy civilisation; and, over all, a ruling Providence extends which sways the destinies of terrestrial races."

DR. LIVINGSTONE.

INTELLIGENCE of the safety of Dr. Livingstone has just reached us from Bombay, and will be welcomed wherever it is made known, both in England and on the continent, and, in fact, wherever the labours of this great explorer are known and appreciated—and where are they not? This confirmation of the veteran traveller's safety comes in a telegram which was received on Wednesday at the India Office from the Governor of Bombay. It reports that a letter had been received from Dr. Livingstone dated Ujiji, May 13, 1869. This letter is nine months' later intelligence from the Doctor than formerly received. We may now, therefore, reasonably presume that the dauntless explorer has surmounted the worst dangers, and that his researches are progressing without any more than natural impediments. We last heard of him from a latitude far beyond the limit reached by Grant, Speke, or Baker, and this ten months since. In these remote regions, far away from family or friends, and practically cut off from all communication with the outer world, Livingstone keeps on his course, untired and undismayed. He knows that the great end and purpose of all his toilings and wanderings is not the glory which they will shed on his name. He knows, too, that it may be long ere the discoveries he has made, the lakes, watersheds, and lands of promise he has mapped out, shall be of practical value to man. But he also knows and feels, as a Christian and a philanthropist, that he is opening up a wide field for the spread of civilisation, and, as a practical man, he knows that there is an abundance of material wealth in the earth and on its verdant slopes and plains for man to develope and utilise. He is the great pioneer pointing out the path, which, however, may not be trod before he has ceased from his labours. But the whole civilised world appreciates, and stands still to admire, the noble self-sacrificing labours of the man in whose safety we now rejoice, and of whose return we once more have every hope.

CONCRETE.

WERE any proof required of the necessity that exists for practical information respecting the proper manner in which to make concrete, it is to be found in the failures that have attended many of the efforts to build with it in the mass or bulk. These are frequently attributed to an imperfect method of constructing the frames, of adopting a wrong principle of dealing with the material, and of hurrying the work. No doubt all of these causes and many others contribute towards the want of success, but the real source of mischief lies in the fact that the concrete is not properly made. From the slovenly, careless manner in which this conglomerate is often made, and the little care taken to ensure that thorough incorporation and amalgamation of the ingredients which is indispensable to a good concrete, the whole mass is frequently utterly useless and valueless. In this condition it possesses neither powers of setting nor of resistance, and whatever superstructure may be reared upon it would be a great deal more secure without a foundation so treacherous. Mr. Reid, whose volume on the "Manufacture of Portland Cement" is well known to the profession, has been for a long time impressed with these facts, and the object of the present treatise* is to afford sound practical rules, the observance of which will always ensure the preparation of a reliable concrete. There are two principal classes or descriptions of concrete. The one is that in which lime constitutes the chief amalgamating ingredient, the other in which a cement is substituted for the lime. It is needless to remark that the latter is the more expensive article, although not to the extent that might be anticipated, because the cement will stand a larger proportion of what our author calls "aggregates" than even the best lime. If we regard lime or cement as the basis of all concretes, then whatever other ingredients may be used they come under the term of "aggregates."

Mr. Reid devotes the first part of his treatise to the "bases" of concrete, commencing with lime. There is a difference to be noticed here in the nature of a concrete made with lime and one made with cement. The former, if properly manufactured, will possess superior cohesive properties to the pure lime, whereas in the latter case samples of pure Portland cement have been proved to be stronger than those mixed with sand or gravel. The use of puzzolana, which is of volcanic origin, commenced in this country with the erection of the Eddystone Lighthouse, and to the success which attended its mixture with various kinds of limes may be traced the subsequent manufacture and introduction of Portland cement, which now plays so important a part in nearly every engineering and architectural work of magnitude. One advantage of puzzolana is that it can be used in its natural condition. At the same time it is beneficial to slightly burn some of the varieties, as they then amalgamate better with lime. Previous to the employment of Portland, Roman cement was that most in favour, but it has been nearly completely superseded by the former material. Roman cement was never a cheap cement for several reasons. Firstly, the "clay balls" from which it is procured were difficult and expensive to obtain; secondly, the cost of carriage was heavy; thirdly, it could not be profitably manufactured on a small scale; and, fourthly, it is not able to bear much sand. In all important works it was used pure, as, for instance, in the Thames Tunnel. This cement may be easily known from Portland, not only by the great difference in colour, but from its inferior weight, which should not exceed 80lb. per imperial bushel. Portland cement may reach so high as 120lb. and even 130lb. per bushel without being of a spurious character, although our author recommends 110lb. as about the right weight. The peculiar property of Roman cement is that it sets very quickly. It is thus very valuable for pointing the joints of a dock wall, or other building exposed to the action of running water, the stones of which have been laid in the ordinary manner. Medina, which is only a variety of Roman cement, may be also advantageously applied in this manner.

The next chapter is an epitome of the more detailed account of Portland cement given in Mr. Reid's former publication, so that we shall pass on to the other ingredients or aggregates. Clean sharp river gravel, such as Thames ballast, is, on the whole, the best description of aggregate, but broken stones, bricks, slag, ashes, and, in fact, almost any hard material reduced to small dimensions, will answer the same purpose. The sharper and more angular the aggregate the better, as it possesses greater binding properties than smooth rounded particles. We have frequently witnessed stones, such as shingle, being used without any preparatory breaking up, or any attempt being made to bestow sharp edges upon them. It is also necessary that an aggregate should not be of a porous, absorbent nature, or it might otherwise abstract from the base, whether lime or cement, with which it is mixed, the water it contains, and so prevent the subsequent induration of the mass. The cause of the setting of limes, cements, and concretes has never been clearly or satisfactorily accounted for, although the supposition is that the lime which in one shape or another exists in them all has a tendency to return to its former condition of a carbonate. Our knowledge on this point is very imperfect, and it is questionable whether it will ever be anything else. It constitutes one of those operations of nature which we can only judge of by their effects. So long as concrete was employed only in the foundations of buildings, there did not exist so great a necessity as there is now for its careful preparation. It ought at all times, and for whatever purpose it is required, to be properly prepared, but since its application to the building of walls, houses, and superstructures generally, a greater degree of skill, intelligence, and care must be employed. The old method of mixing the ingredients by manual labour is now superseded by the more modern appliance of machinery, so that, provided the ingredients, bases, and aggregates be of good quality, the concrete will necessarily be equally good. We fully endorse the advice of the author, which prohibits any but ground lime being used for making lime concrete, employing the latter term in contradistinction to cement concrete. A great error in the preparation of concrete is the superfluous quantity of water used in the mixing. It is not an uncommon circumstance to witness a mass of concrete quite drowned in water, and this, too, when it is intended to be deposited in a wet situation. We remember once having to lay concrete in a very wet foundation, and we simply mixed it *in situ*, which answered remarkably well. Both the Roman and Portland cement may form the base of a cement concrete, but the former is now but seldom employed. It nevertheless is valuable in situations where there is running water to contend against, from the greater rapidity with which it sets, but in general utility and application it bears no comparison with the more recently manufactured article. After describing the various machines by the aid of which the labour formerly requisite to make concrete is now obviated, Mr. Reid concludes his volume with some general observations of a practical character. In a sanitary point of view, the application of Portland cement concrete to the erection of houses would be attended with considerable domestic advantages. Damp walls are the cause of more sickness in young and old than people are probably aware of. What is required in all the houses of the poorer class are walls that will wash and yet not retain damp, and this could be obtained by the employment of Portland cement concrete. Plates are attached to Mr. Reid's volume, containing illustrations of moulding, testing, grinding, and concrete-mixing machines, and the treatise is calculated to be of the greatest service to the practical man. All builders should have it in their possession, and those who have anything to do with the purchase, sale, or application of limes and cements

* "A Practical Treatise on Concrete, and how to make it, with observations on the uses of cements, limes, and mortars." By HENRY REID, C.E., author of a "Practical Treatise on the Manufacture of Portland Cement." London: E. and F. N. SPON, 48, Charing Cross. 1869.

will find in it rules for their guidance which will be of pecuniary importance to them. The publishers have brought out the book in their usual excellent manner, and our readers who are interested in its contents have only to purchase it to be satisfied of its merits.

TELEGRAPHIC NOTES.

THE Postmaster-General has recently given his sanction to the adoption of the Army and Navy telegraph code, by means of which telegraphic correspondence is carried on in cypher. The code system is the invention of Major Bolton, and its simplicity and ingenuity are seen from the example given below. The principle upon which the system is based consists in giving an individual number to the most frequently recurring sentences and phrases in a language. The code embraces every conceivable sentence and phrase the English language contains. These stand in alphabetical order, numerically arranged under the head of a certain page. As an example of its working we will assume that the following message is to be transmitted:—"Cotton is falling and I should not advise you to buy." On turning to the letter C of the code, we find the word Cotton at page 094, and the exact sentence we require numbered 07, so we write 09407. In this way the message is forwarded in code, beyond the least chance of being tampered with or mutilated. The advantage in favour of the code is that those using it can ensure perfect secrecy for their despatches, and it is applicable to every written language. A comparison of the Bolton or Army code system with the Morse system is afforded by a series of experiments which were conducted on board the "Great Eastern" in 1865 in the presence of the most eminent English and American electricians of the day. As a specimen of the results we may take the following:—Three identical messages were transmitted through the whole length of the Atlantic cable by means of the Bolton code, and also by the Morse system; the time required for their transmission and the number of symbols used was as follows:—Number of groups of figures by the Bolton code, 56; number of letters by the Morse system, 611; time by the code, 27min. 45sec.; time by the Morse system, 74min. 30sec. It will thus be seen that the Morse system required about three times the number of symbols and nearly thrice the time requisite for the transmission of the same messages by the Bolton code.

The directors of the Telegraph Construction and Maintenance Company have called a meeting of the shareholders for the 30th inst., for the purpose of considering the propriety of reducing the capital of the company—which now consists of 37,350 shares of £20 each fully paid up, being equal to £747,000. It will be remembered that at past general meetings of the shareholders the chairman, in referring to the accounts, pointed out that a considerable portion of the capital was represented only by the goodwill of the businesses purchased from the Gutta Percha Company, and Messrs. Glass, Elliot, and Co., and that the board desired to reduce this item as early as possible, and to leave the capital at the amount which would be represented by actual and available property and securities of the company, and the shareholders expressed their approval of this course. The satisfactory operations of the company during the last eighteen months enable the directors in their report to recommend the shareholders to begin to carry out this policy at the present time. It will therefore be proposed to the meeting that £4 per share of capital should be returned to the shareholders at the end of the present year, and that as soon as practicable a further return of capital of £4 per share should be made, leaving £12 per share paid up, or a total of £448,200, which will be fully covered by buildings, plant, stock, and stores of the company. If the shareholders sanction this arrangement, the necessary legal steps will be taken under the "Companies' Act, 1867," to reduce the nominal amount of the capital of the company, so as to leave the shareholders free from liability for future calls.

The report of the West India and Panama Telegraph Company, to be presented to the shareholders at their first meeting to be held to-day, states that the number of shares allotted is 43,710, which, with the 5,000 fully paid up shares to be handed to the contractors in part payment for the cable, represents an available capital of £487,100. The manufacture of the cable has been commenced, and 498 miles have been already completed to the entire satisfaction of the company's engineer. The directors anticipate that the greater part of the cable may be sent out by March next. A communication has been received from the Governor-General of the Leeward Islands, expressing a desire that those islands should be included in the company's scheme, and negociations are in progress for settling the terms.

The Council of the Society of Arts, looking at the fact that the Government have now taken under their control the whole of the telegraphs of the United Kingdom, have appointed a standing committee of the Society to watch the interests of telegraphy generally, as well as to promote the progress of the science and the efficiency of the system. The following gentlemen have been invited to serve on this committee:—Lord Sackville Cecil, the Earl of Caithness, F.R.S., Sir W. Fothergill Cooke, Mr. Latimer Clark, Mr. Hyde Clarke, D.C.L., Colonel Glover, Professor Guthrie, Sir J. F. W. Herschel, Bart., F.R.S., Professor W. A. Miller, F.R.S., Mr. C. W. Siemens, F.R.S., Professor Tyndall, F.R.S., Sir William Thomson, F.R.S., Mr. Cromwell F. Varley, and Sir Charles Wheatstone, F.R.S. Telegraph wires are to be carried from the Great Eastern Railway goods station at Wisbeach to a house in Bridge-street, where the telegraph business of the town will be conducted on and after January 1. The wires in connection with the Oundle Post-office will form a junction with the London and North-Western Railway at the Ashton crossing. The distance from the point of junction to the post-office is about a quarter of a mile. An additional room is being fitted up at the Boston Post-office, which will be entirely devoted to telegraphic business. Posts and wires are being erected between the railway stations and the post-offices of Louth, Gainsborough, and other Lincolnshire towns.

We read in the "North German Correspondent" that the project of leasing a wire of the submarine telegraph between England and America for the exclusive use of Germany has been brought to a successful issue. The old cable will now pass entirely into the hands of the German company, its owners only reserving the right of using it when their own is injured. The communication between Valencia and Berlin via London will be also carried on by a line exclusively under the management of the German company.

The following telegram having reference to the Suez Canal and the telegraph has been received by the Telegraph Construction and Maintenance Company:—"Nov. 20, 11 a.m. "Hawk" at Suez, after most successful passage throughout. Make your arrangements for passing Suez section (of cable) through canal. Briscoe will send you soundings, which have been most carefully taken. Seventeen feet will easily pass."

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

UTILISATION OF THE RETURN CURRENT IN SUBMARINE CABLES—ARTIFICIAL IVORY—PRESERVATION OF TELEGRAPHIC POSTS—METEORS.

A COMMUNICATION to the Royal Academy of Sciences of Brussels, by M. Zantedeschi, offers an idea which we present to practical telegraphists for what it is worth. Regarding, as has been often said before, a submarine cable as a Leyden jar, the author points out that when the inner insulated wires convey a message from Europe to America, the message is re-conveyed from America to Europe by the wires forming the outer portion of the cable, and he proposes to establish instruments at each end to receive this return message, so that the operator may see that the telegram has been correctly transmitted. The details of the author's plan are not before us; but electricians will be able to judge whether or not his idea is worthy of consideration.

A process for producing artificial ivory has been published in a German journal. The inventor, whose name for the moment escapes us, makes a solution of indiarubber in chloroform and passes chlorine gas through it. After this, he heats the solution to drive off any excess of chlorine, and also the solvent, whereupon he has left behind a pasty mass with which it is only necessary to incorporate sufficient precipitated carbonate of lime or sulphate of lead, or, indeed, any other dense white powder, to obtain a material which may be pressed into moulds to form whatever articles may be desired. The details of this process are obviously incomplete, and the success of it may be doubted. Only good and well masticated rubber could be employed, and even then a dilute solution must be made, and any earthy impurities allowed to deposit. In the next place, we are doubtful of the bleaching action of chlorine on rubber, and, moreover, chloroform is, under some circumstances, decomposed by chlorine. Lastly, it is clear that, to obtain a hard material at all resembling ivory, it would be necessary to make a "hard cure," for which a considerable proportion of sulphur would be required. The simple purification of indiarubber by means of chloroform would, however, furnish a mass of a very fair colour.

A Belgian report on the preservation of telegraphic posts decides that chloride of zinc is the best and cheapest agent to employ. It is admitted that differences in the soil in which the posts are set make considerable differences in the preservative action of the matters employed. Thus, while sulphate of copper succeeds admirably well in some situations, it is shown that calcareous soil tends to produce a decomposition of the sulphate, and a very sandy soil draws out the salt from the wood. Creosote, the report says, possesses many advantages, and in particular is very cheap, but the Belgian administration consider that these advantages are more than balanced by difficulties in manipulation, and they have given up the use of creosoted posts.

The meteoric showers of the 13th and 14th were concealed from view in this country by a thick canopy of cloud. Some glimpses of them were caught at Luxemburg by an eminent observer, M. C. C. Gravier. We shall no doubt have further accounts from the French astronomers who went to the south of France to observe, where, however, it is likely that although no clouds intervened the brightness of the moon may have rendered all but the nearest to the earth invisible. Awaiting those observations, we turn for a moment to some recent speculations on the phenomena presented by these remarkable bodies. The incandescence of meteors which alone renders them visible has in general been attributed to the heat developed by friction against our atmosphere, but it is now suggested by M. Govi, who is supported in his opinion by Regnault, that the heat is really developed by the compression exerted on the air by the weight and velocity of the stone. This idea is also adopted by M. Delauny, who starting with it explains all the phenomena attending the fall of a meteoric stone, the explosion more or less violent which is generally heard, the fact that the stone falls to the earth with a velocity relatively slight when compared with the rate at which it traverses the sky, and, lastly, the circumstance that the fragment is entirely covered with a vitrified crust. The compression of the air exerted by the meteor must produce a resisting pressure on its anterior part, which M. Delauny estimates as at least equal to a pressure of twenty-two atmospheres, and this he considers sufficient to produce the rupture of the stone. When the rupture takes place the small fragments are driven back behind the principal mass, and thus a vacuum is produced and air rushing in produces a noise just as when a cannon is fired. At the same time the initial velocity of the fragment is destroyed, consequently it falls to the earth with only the force determined by its own weight. Lastly, the extreme compression of the air raises the temperature sufficiently high to produce a superficial fusion of each fragment, and hence the enamelled surface observed.

We may add to this some highly interesting remarks by M. Stanislaus Meunier, on the Deesa meteoric stone, in which he finds evidence of eruptive rocks, such as we know on our globe, and from which he draws most important consequences. To M. Meunier meteoric stones are fragments of a star or world in ruins. The sun, he conjectures, is an example of a star in its first stage of evolution, our earth is an illustration of the second stage, that of life properly so called, while the moon is to be considered a dead world, and meteors the result of the decomposition of some other body. It is unpleasant to read that the moon shows signs of dropping to pieces, but possibly it may last our time.

THE LOW WATER BASIN AT BIRKENHEAD.

AT a meeting of the Institution of Civil Engineers held November 9, 1869, Mr. C. H. Gregory, president, in the chair, the discussion upon Mr. Ellacott's description of the low water basin at Birkenhead, which had been adjourned from the last session, was resumed and concluded.

In the course of the discussion it was remarked that the Low Water Basin should be of the utmost value to the commerce of the Mersey, inasmuch as the bottom of the basin was 12ft. under low water of spring tides, while the sill of the Princes Dock, at Liverpool, was 2ft. 10in. above such low water. The works, however, as actually carried out, differed materially from the plans proposed by Mr. Rendel, as would be seen from the following figures:—

	Mr. Rendel.	Actual.
Area of basin	37 acres ...	14 acres.
Sectional area at entrance to river, at low water	4,200 sq. ft. ...	3,600 sq. ft.
Aperture of sluices ...	1,820 ,, ...	826 ,,
Ratios of areas of sluices to area of basin at entrance, at low water	1 to 2·3 ...	1 to 4·33

From this it would appear that, in order to produce a given flow from the basin into the Mersey at low water, the velocities through the sluices must, by the actual plan, be 1·85 time as great as those intended by Mr. Rendel; and, if the action of a stream of water were as the square of the velocity, the destructive effect would be about 3½ times greater. It was further observed that the discharge from two sets of sluices, separated by an interval of 120ft., differed essentially from the continuous sheet advocated by Mr. Rendel; and that the result of such differences would lead to eddies and foul currents. Again, although the levels of the sills of the sluices were about the same as in the original designs, yet, in place of the water having a short run through the sluicing chambers, the inner ends of the bottoms of these passages were at a level of 8ft. below the Old Dock sill, and distant, on an average, 265ft. from the paddles, the sills of which had been placed at a level of 18ft. below the Old Dock sill, thus creating a fall outwardly of 10ft., and from the sills of the paddles to the extremity of the apron another fall of 3ft., making together 13ft. from the inlet side of the sluicing passages to the bottom of the low water basin. It was argued that such a fall must have a tendency to tear up the bottom at the extremity of the apron. It was also pointed out that the use made of the sluices, as recorded in the paper, was entirely at variance with the use proposed by Mr. Rendel, who had repeatedly and distinctly stated that the sluicing was only to remove the material brought in by the tides, say about 1-10in. of newly-deposited silt every twenty-four hours. Now, it was stated in the paper that the actual sluicing operations had been directed to the removal of a depth of 32in. of clay, and the quantity displaced on fifty-six occasions was estimated at 106,100 cubic yards, which was about equal to 1in. over the whole surface of the basin, or ten times the amount originally contemplated. Further, the velocity of efflux was never intended to exceed 5·08ft. per second, whereas, on the 18th, 19th and 20th of August, 1864, it was calculated that the velocity of discharge had been 30·87ft. per second, while if the whole of the fifty-six days were taken, it would be found that the average velocity of discharge was 26·54ft. per second. It was not stated to what height the sluices were drawn, but it was presumed that they must have been opened to their full extent. In making trial of such an important work, it would have been judicious to draw the sluices about 18in., or a little more, at one time, opening some of them, keeping others closed, and interspersing the apertures in such a way as to cause the current to act in the most efficient manner throughout the low water basin. If this had been done it was believed that a current of 2 miles per hour would have sufficed to clear the basin of all ordinary deposits.

On the other hand, it was contended that in 1856 the Parliamentary plan of Mr. Hartley abolished the low water basin, and substituted in its place an outer dock, with locks, and a small entrance basin recessed back only 400ft. from the Mersey; but the low water basin was subsequently forced upon the Liverpool Corporation by the railway interests. The original idea in treating Wallasey Pool was that it should form a great highway leading to docks to be ultimately found on its margin. In 1858, however, an alteration was made, and Wallasey Pool was no longer regarded as a highway, but as a great dock. Obviously, then, what would apply in the one case would not apply in the other. It was asserted that the mode of sluicing suggested was inapplicable, as far as the working of the dock was concerned, and that it would have failed to keep the low water basin open. It was maintained that there was no volume of water available to produce the requisite current, and therefore that the Liverpool authorities had acted wisely in determining to abandon the project, and at once to make a dock, with a small tidal basin, so far recessed from the Mersey that it could be kept open by sluicing from the gates above.

It was stated that throughout the controversy in 1844, it was distinctly urged that it was not intended that the water should have an inclined downward action, but that it should issue from the sluices horizontally. It was alleged that the sluicing had failed, from the water having been projected downwards, which, so projected, followed the same law as a solid mass; it was reflected upwards, and produced an upper current. It might be quite true that in 1853 it was difficult to get water to maintain the low water basin; but the conditions were very different in 1844 and in 1853. It was proposed, in 1844, that the float should be filled at every tide to the level of the tide of the day; and inasmuch as the indraft from the Mersey would have been at the rate of ½ a mile per hour during the six hours of flood tide, the water would only carry material due to that velocity. But the rate of discharge was to have been 2¼ miles per hour—a velocity amply sufficient to remove particles brought in by the flood.

In seeking for the cause of the failure of the sluicing operations, it was contended that the first thing to be regarded was the work to be done, and then the means provided for doing it. The primary object was to set in motion the body of water contained in the low water basin. This was 1,750ft. in length, and varied from 300ft. to 400ft. in width; and the depth when the sluicing was commenced was 19ft. 4in. The weight of the water to be set in motion, or simply to be started, was 338,275 tons; and for this purpose twenty sluices were provided, having a combined area of 826 square feet, with a head of water against them at the first sluicing trial of 14ft. 3in., producing a total pressure of 336 tons, or less than the one-thousandth part of the load. This was a greater disproportion than was found to exist in other instances where a load had to be moved with a comparatively small power. Some intermediate gearing was wanted between the power and the weight; but in the work as carried out this had not been supplied. The 336 tons of power seemed to have been employed against the 338,275 tons of load at a velocity of about 17 knots per hour; that had simply had the effect of disturbing portions of the water, and throwing the water into a state of great confusion. Gradually the water appeared to have attained a more uniform motion, but at the end it resembled a series of eddies and strong currents rather than a stream.

With regard to the question of sluicing in water of considerable depth, it was observed that Mr. Rendel had evidently contemplated the removal of the deposit, not by the direct sluicing and violent action of the water rushing out of the Great Float, but by setting in motion, gradually and at a much lower velocity, the large body of water which had been previously collected, or which remained in the low water basin. The silt in the Mersey was of a very binding quality, and when it had once aggregated it was difficult to move it except by great violence. There were sandbanks in the Mersey which resisted a velocity of from 8ft. to 12ft. per second; and therefore it was that Mr. Rendel had proposed very frequent sluicing, so as to prevent any serious amount of deposit and of aggregation taking place. Upon the general question of sluicing it was remarked that if it were intended to effect scour by setting a large quantity of deep water, or at least a substratum of water, in rapid motion, it would be utterly impossible. No doubt, in the immediate proximity of the aperture of emission, the water would issue and would flow for some distance with a velocity due to the head of water with which it was propelled—in the case under consideration from the interior of the Great Float. But there were causes which prevented that action continuing to any considerable distance. In the first place there was the enormous friction between the moving water and the immovable bottom over which it flowed. Besides that, a volume of water moving with a high velocity through a body of water in a nearly qui escent state encountered a large resistance. When the endeavour was made to sluice the bottom of the Great Float at the Birkenhead Docks, the water rose up, spread out until it assumed almost an umbrella shape, and moved the deposit away for a short distance; then, as the water lost its velocity, the deposit again collected in banks, and the sand accumulated and aggregated, while a succession of waves was produced in the basin. It was admitted that, under ordinary circumstances, it was possible to effect sluicing provided a sufficient quantity of water was obtained to give that general velocity, not bottom velocity merely, necessary to move the particular material to be dealt with; but it was impossible to establish a bottom velocity of great amount for any considerable distance. The opposite was indeed the case,—that the velocity of the water at the bottom was always less than the velocity at the top, except in the immediate neighbourhood of the sluicing operations.

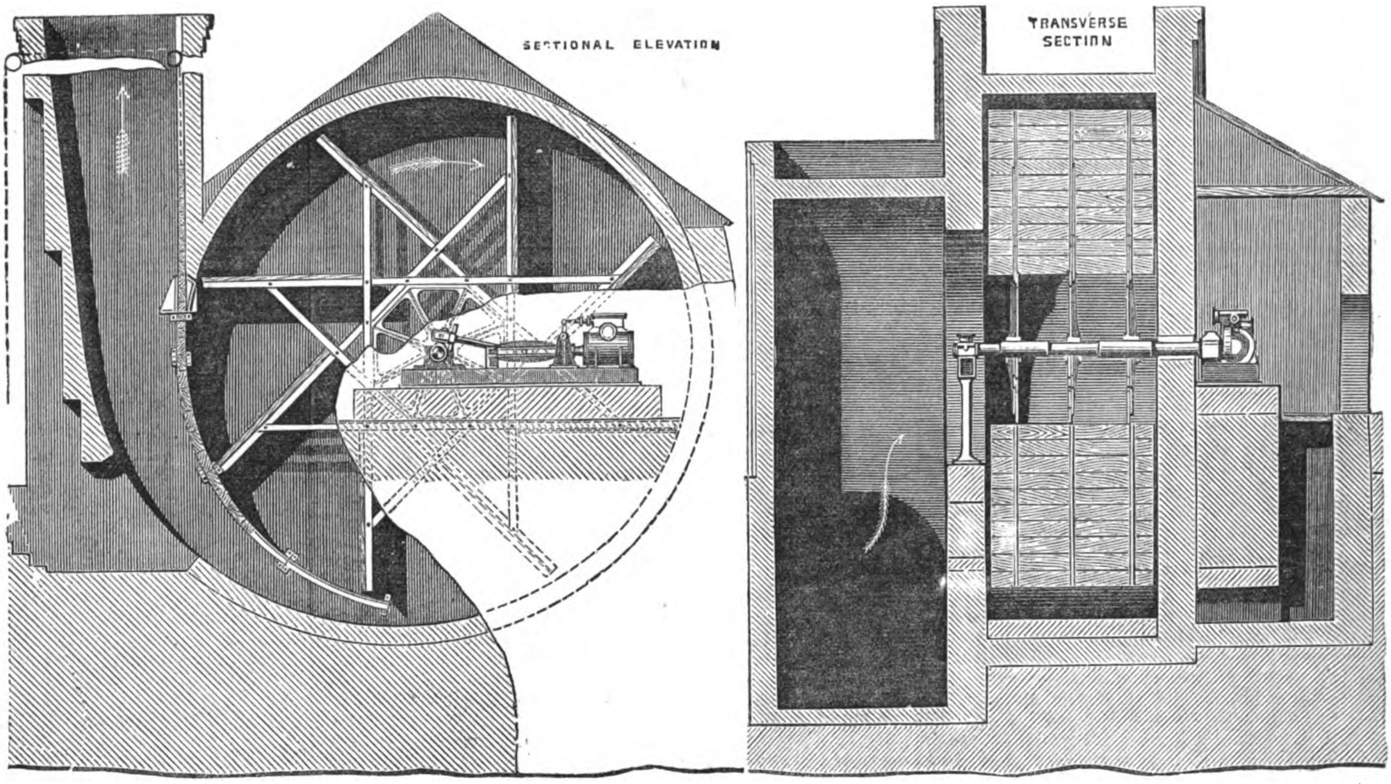
THE METEOROLOGICAL SOCIETY.

THIS society commenced its session of 1869-70 on the 17th inst., by holding the first ordinary meeting at the Institute of Civil Engineers. C. V. Walker, F.R.S., President, occupied the chair, and among the fellows present were J. Glaisher, F.R.S., secretary, Drs. Brooke, Mann, Tripe, and Trentler, Messrs. Symons, Eaton, Doggett, Cyrus Field, Perigal, Brewin, Dines, Gaster, and Mackenzie. Six gentlemen were balloted for, and duly elected fellows. The first paper read was from the pen of Dr. Fielding, of Tunbridge, on the "Weather of the Year 1868." After describing the position of his instruments and the shading of the thermometers, the author proceeded to remark on the weather of each month. Attention was specially directed to the excessive and protracted heat of the remarkable summer, but many of the temperatures recorded were so extremely high, and so much in excess of those recorded at neighbouring stations, that the meeting, after some discussion, requested the secretary to communicate with the author in order to ascertain what were the errors of his instruments, and whether they had been compared with standards. Mr. Symons remarked that, with regard to the accuracy of Dr. Fielding as an observer, no doubt whatever could exist, and that to all appearance the instruments were well placed, though perhaps scarcely sufficiently shaded from the sun's rays in summer. Mr. Glaisher also said there could be no question so far as observing went, but he much desired to examine the instruments, since a maximum temperature in the shade exceeding 101deg., and several readings exceeding 95deg., in one summer, were not only unprecedented in this country but unsupported by observations made in all parts of the kingdom. After some further remarks by various gentlemen, Mr. Glaisher made a brief verbal statement as to his having, during his late balloon ascents, experienced temperatures at very considerable elevations above the earth's surface higher than those just above ground, the law appearing to be that in calm weather the stratum of air nearest the earth is warmer in the daytime but colder at night than that at (say) half a mile high. This, he contended, was entirely contradictory to the old theory of a regular decrease of 1deg. for each 300ft. of altitude, which theory appears to have no support from facts under any circumstances. Those who took part in the discussion all appeared desirous of having a larger basis of observations for forming an opinion on the subject. It is to be hoped that Mr. Glaisher will submit his entire series of balloon observations to the society, and so give others an opportunity of discussing them. It is well known that Mr. Glaisher's balloon series of observations are almost the only reliable data obtained for the higher regions of the atmosphere in this country. Aëronauts generally sadly misuse the opportunities they have for enriching meteorology. The only other paper which attracted any notice was one by the Rev. Mr. Previté, on the "Readings of Barometers not Suspended Perpendicularly." The author had calculated the errors which would be produced by different degrees of divergence from the vertical. The paper was very properly objected to by some of the fellows on the ground that it gave countenance to placing instruments badly, and that meteorology is always burdened with difficulties enough to overcome without imposing on itself erroneous barometrical readings to correct. The paper which had been announced from Mr. Bloxam, of Newport, on "Lunar Influence upon Rainfall," was not read.

On the whole, we congratulate the fellows upon their determination to exclude worthless papers from their proceedings, but as an inauguration of the session, the meeting was not at all promising of any revival of this rather lethargic society.

THIRTY-FEET GUIBAL FAN.

BY MESSRS. BLACK, HAWTHORN, AND CO.



THE MECHANICAL VENTILATION OF MINES.*

By Mr. William Cochrane.

It must be admitted that in the great advance which has been made in the development of mining enterprise, and looking to the future requirements of our local coal-fields, adequate ventilation is not inferior in importance to any of the problems which the mining engineer has to solve. The earliest records of mining make us acquainted with the readiest mode of ventilation, no provision beyond the natural conditions being adopted; and so long as mines were only worked to a very limited extent by levels or "adits," or if by shafts, of very small depth, the natural system was found to answer all requirements; only there was this disadvantage—that, with thermometrical variations, the determination of the current of air was dependent on the average temperature of the mine, being above or below that of the external atmosphere, a condition constantly varying and interchanging throughout the year, and, therefore, not permitting any certainty of action in the direction or quantity of air which could be used for ventilating the mines. This system is still used in mines of limited extent, and where, from the nature of the mine, very small resistances are offered to the current of air circulating. In some cases, under these conditions, as in the Staffordshire "thick coal" mines, the determination of the air into a particular course is often ensured by placing a fire lamp in the upcast shaft. Such a contrivance, however, can only produce a very small effect, and is, therefore, of limited application. On a larger scale, however, this principle has formed the most generally adopted system of mine ventilation in this country, namely, that of the furnace.

Much discussion had arisen as to the best system of furnaces and the most economical mode of feeding them with air. The following are the results of some recent experiments that have been made at different collieries in the northern coal-fields under various conditions and depths of shafts, extent of workings, and thickness of the seams of coal, and are reduced for the purpose of comparison to the duty that 1lb. of coal consumed effected per horse-power on the air circulated in the mine; the pressure was indicated by a water gauge placed in the mine, and therefore represented only the work done in overcoming the friction down to the mine, and exclusive of the work required to overcome the friction resistance of the two shafts. The general result of the experiments was that that duty varied from 37lb. to 101lb. of coal per horse-power on the air, taken upon currents of air ranging from 40,000 to 120,000 cubic feet per minute. Depth of shaft is the most important consideration for the efficient application of a furnace. There are other conditions, however, which it is necessary to secure, namely, that the shaft be dry, and that it be lined with a good heat-retaining material. It is considered a fair estimate of the economic value of the average conditions in which furnaces are worked that only one-fifth of the heat due to the combustion of the coal is utilised. There are many objections besides the small useful effect to the use of a furnace which cannot be overcome, and which form a constant source of cost attendant upon it, namely, the necessity of cleaning the flues and the consequent suspension of the active ventilation of the mine; the inconvenience, and in some cases the impossibility, of using a shaft highly heated, and often full of smoke, for any other purpose than as a ventilating shaft; and the serious damage done by the products of combustion to cast-iron tubing, timber, pumps, or wire ropes, where winding is carried on in the upcast shaft, especially where the shaft is damp. If the conditions are unfavourable for the use of a furnace, such as shallow shafts and heavy resistances to be overcome, the furnace is then quite unable to compete with a good mechanical ventilator in economical effect. The limit of the furnace as a ventilating power is soon reached where the resistances offered by a mine are heavy, and this objection naturally led to the adoption of other means to meet the conditions under which the furnace would fail to afford a sufficient ventilation.

Machines for blowing fresh air into or exhausting the foul air from mines were adopted in the very earliest times, especially abroad, where the conditions of the seams are such as required more efficient ventilation than the furnaces supplied. Hence it is that mechanical ventilators are very numerous abroad, while in this country, until very recently, they were quite exceptional. In a table compiled by Mr. J. J. Atkinson, Government Inspector for the Durham coal-field, has been shown the depth at which furnaces are estimated to be equal to ventilating machines in point of economy of fuel, assuming that the sources of loss are of the same extent in each case, that is, the loss of fuel in furnaces by cooling in the upcast, and in ventilating machines the power expended in overcoming the useless resistances, and that the ventilating machines utilised 60 per cent. of the engine power. The general result is that the minimum depth at which the economy by the two plans is equal is 960yds., with an average upcast temperature of 100deg. Fah., and a depth of 1,130 yards, with 200deg. Fah. temperature, estimating a consumption of 8lb. of coal per hour per indicated horse-power of the engine. A recent calculation by M. Guibal, of Mons, deduces the following comparisons—that if a furnace in a 12ft. shaft, 400 yards deep, circulate 53,000 cubic feet of air per minute under the total resistances represented by 3¾in. water gauge, and an average excess of upcast temperature of 108deg. above the downcast, with a duty of 31lb. of coal per horse-power in the air estimated upon the total resistances, then a mechanical ventilator utilising 60 per cent. of the power enployed would, under the same conditions, have a duty of 11lb. of coal per horse-power on the air, being a saving of 64 per cent. At a depth of 550yds. to circulate the same volume, the duty of the furnace being 22lb. of coal, that of the mechanical ventilator would be 11lb., being a saving of 50 per cent.

The author then classified the mechanical ventilators which had been used under two heads—first, those working by centrifugal action; and second, those working as pumps. Of those of the first class, one had been described at the last meeting—the Guibal ventilator at Crudley Colliery, Staffordshire. The largest example of that class erected in this country will be seen at the Thrislington Colliery. It is 36ft. diameter, and 12ft. in breadth, driven by a horizontal cylinder 30in. diameter and 30in. stroke. The ventilator has only been recently erected, and is not yet ventilating any large extent of working, but some experiments have been made with it, from which the following results have been obtained. The regulating shutter was not properly adjusted so as to give the best results of working, and the drift to the upcast shaft was too small for accurately increasing the current of air, amounting to 80,000 cubic feet per minute. With 54 revolutions per minute a water gauge of 2½in. was maintained at the inlet; with 70 revolutions a water gauge of 4½in.; and with 80 revolution as water gauge of 6¼in.*

After giving the results of other Guibal ventilators in operation, the paper continued.—In order to make a fair comparison of the Guibal ventilator with the furnace, the following case of the Pelton Colliery, Durham, is given, as it is the only one where the data have been accurately ascertainable respecting the replacing of the furnace by this mechanical invention. In this case the duty obtained by the furnace was 102lb.

* Institution of Mechanical Engineers.

* Our engraving illustrates a 30ft. Guibal fan, constructed by Messrs. Black, Hawthorn & Co., of Gateshead-on-Tyne.

of coal per hour per horse-power in the air estimated, on the water gauge of 1 1-10in. indicated in the mine, and a current of air of 35,000 cubic feet per minute; and the duty was reduced by the ventilator to 20lb. per hour per horse-power with a current of 54,000 cubic feet, and a water gauge of 2in. indicated in the same position. This shows a saving of fuel by the adoption of the Guibal ventilator in place of the furnace, amounting to 80 per cent. The class of ventilators to which the Guibal belongs is that of centrifugal action, and in the same class may be mentioned the Biram, Nasmyth, Brunton, Rammell, and Waddell ventilators. A Biram ventilator (similar in principle to the Nasmyth, with the exception of the vanes being inclined to the radius) the writer has experimented upon at Tursdale Colliery, Durham, and found that only 12½ per cent. was utilised of the gross power supplied from the steam boilers; and from experience with other open running fans he considers that percentage cannot be materially exceeded with any form of open fan without a casing. A Waddell ventilator, recently erected at Pelton Colliery, utilises only 39 per cent. of the power applied; and a Rammell, at Framwellgate Moor Colliery, does not exceed 40 per cent. of utilised power. The Guibal utilises 60 per cent. of the power applied.

Except the Guibal, all the other ventilators of this type discharge throughout the entire circumference; but that this is a defect can be inferred from the fact that if such a fan running open have the access of air into its centre stopped, great power will still be required to make it revolve, though no useful work is done. The useless work done upon the external air in this case is done to a diminution of useful effect, when the fan is exhausting air supplied at its centre from any mine drift or passage. It was anticicipated that the Waddell ventilator would obviate this defect by arranging the air passages through fans of a gradually decreasing section from the centre to the circumference, so that the velocity of rotation at any point multiplied by the sectional area of passage at that point should be constant, thus filling up the fan with issuing air, and preventing the possibility of re-entries. In this case the re-entries cannot be seen as in the Biram, where the eddies of air all round the circumference are easily distinguished, but that they do evidently arise is proved by the low power utilised. The Brunton, which closely resembles the Waddell and the Rammell, cannot be expected to yield any better results. By the kind permission of Mr. Daglish, the results of a Rammell ventilator, recently erected at the Framwellgate Colliery, are here given:—Diameter of ventilator, 22ft., with 20in. steam cylinder, and 102 revolutions per minute; volume of air, 53,600 cubic feet per minute, with a water gauge of 2¼in.; result, 40 per cent. utilised. One of the chief reasons of the low useful effect of these exhausting fans is that they are exposed throughout the entire circumference to the external air, which rushes in behind the vanes to supply the vacuum formed by their revolutions; but this vacuum ought to be supplied only from the mine to be ventilated, and it was this consideration, and the practical proof that this injurious effect was inherent in open running fans, that led to the casing of the Guibal ventilators and discharging the air at only one part of the circumference. This step, however, was attended with the objection that the air was discharged with a high velocity, viz., the velocity of the periphery of the fan, and carried away with it a most important store of force, the partial utilisation of which has been effected by adapting the principle of erased tubes to the expanding chimney, in which the casing of this ventilator terminates. The air entering its base at a high velocity leaves the chimney at a reduced velocity proportionate to the increased area of the outlet, and in this action restores a considerable amount of power it would otherwise carry off. An adjustable shutter was next found necessary, in order to regulate the size of the outlet and the various conditions of the volume of air required, and resistances. A series of very interesting experiments had been made, showing the steadily-improved results obtained from the ventilator, as the casing chimney and shutter, in its accurate adjustment, were consecutively added.

Generally, as to the powers supplied from the steam boilers for working these ventilators, 60 per cent. was found to be utilised; but it must be noted that this amounted to at least 80 per cent. of the power actually transmitted to the ventilator, as one-fourth of the boiler power must be allowed for the loss due to the friction and imperfection of the steam engine. One of the ventilators (of which several examples were now in use in this country of 36ft. diameter) had been recently started in Belgium of 40ft. diameter, but detailed experiments had not yet been made upon it. It was arranged to work at the speed of 80 revolutions per minute, producing a ventilation of 150,000 to 200,000 cubic feet of air per minute, under a depression of water gauge of about 7in., which was certainly the maximum requirement of any known condition of mines. Indeed, there could be no question that any practical requirement in the ventilation of mines could be satisfied by this system, and it could not be surpassed in simplicity of construction, small liability to accident, and the little wear and tear to which its working parts were subject.

The paper next pointed out peculiarities in the Guibal ventilator—as to the concentric form of the casing, and as to the curving of the vanes—and it then dealt with the second class of mechanical ventilators—that in which the principle of variable capacities, as in the pump, was involved. Struve's air-pump ventilator was the best known of the class, and consisted of two gasometer-formed pistons working in rings of water, alternate upward and downward strokes drawing air from the mine and forcing it into the atmosphere by means of suitably arranged valves. The Struve was, when well constructed and in good order, capable of producing a very satisfactory exhaustion, but for certain reasons it did not offer the advantages for mine ventilation which the centrifugal action fan did. The usual effect was from 40 per cent. to 45 per cent. of the boiler power, when all the working parts, and especially the air valves, were in good condition. In conclusion (to quote the words of the paper), the economy of fuel, if neglected hitherto, has now become of paramount importance. To increase the amount of air in any given time the mine requires the consumption of an increased quantity of fuel, proportionate to the cubes of the volumes; thus, for twice the volume eight times the fuel. Hence the best system of ventilation is that which, under the same conditions of mine and the same amount of first outlay, produces the maximum work for 1lb. of coal consumed, so long as such ventilation compares satisfactorily with any other in the points of durability and cost of working, and possesses the quality of adaptability to all the varying conditions which are met with in mining operations.

THE PATENT LAWS.

On Tuesday evening, a crowded meeting of members of the Waverley Club and others was held at the Arundel Hotel, under the presidency of Mr. Samuel Dickins, M. Arch. Assoc., to consider the working of the patent laws. Among the gentlemen present were Mr. Edward Field, C.E., M. Inst. M.E., Mr. Burton, Mr. Jones, Mr. Humphreys, Mr. Hamer, and others. The opening speech was delivered by Mr. W. Lloyd Wise, who pointed out the important and beneficial effects to the public of patent privileges in promoting the progress of the arts and manufactures of this country, and proposed the following resolution:—"That the granting of exclusive privileges to inventors as rewards for their inventions tends to promote the commercial prosperity of the kingdom." An amendment was moved by Mr. W. G. Dickins, but, after considerable discussion, the resolution was carried with acclamation, and the proceedings terminated with a vote of thanks to the Chairman.

The value of the gold imported into the United Kingdom from Australia and New Zealand amounted in September to £791,400 as compared with £875,486 in September, 1868, and £586,357 in September, 1867. For the nine months ending September 30 the receipts were valued at £5,942,949, as compared with £5,236,729 in the corresponding period of 1868, and £3,863,970 in the corresponding period of 1867. Favourable accounts have been received of late from the diggings and quartz reefs of New South Wales. The Trunkey Creek Quartz Crushing Company has so far progressed that part of its machinery was on the ground at the last dates; it was expected that the machinery from the vicinity of Carcoar would also be shifted to Trunkey. The average yield from the Emew Creek reefs keeps up well, while the prosperity of the district has been maintained by the opening up of several alluvial areas, which have all given payable returns.

FREEZING AND ICE-MAKING MACHINE.

Attention has lately been given in several quarters to the artificial production of ice and cold. The latest example before us is that illustrated in the accompanying engraving, and which is the patented invention of Mr. Franz Windhausen, C.E., of Brunswick. It will be perceived that the invention relates to that class of freezing and ice-making machines in which atmospheric air is compressed, then passed through a condenser, and afterwards expanded again to remove the heat, or, in other words, to produce cold, but which machines have hitherto been limited in their cold-producing properties by the degree of expansion to which the air is subjected, and by the temperature of the cooling water employed. In the present case, Mr. Windhausen constructs a machine of small compass which with one constant degree of expansion of the air employed produces any requisite degree of cold, which can be regulated to the greatest nicety by the hand of the attendant by means of graduated adjusting valve mechanism.

Mr. Windhausen employs a single double-acting cylinder, which is capable of compressing the air on one side of the piston and of expanding it on the other. The air is first admitted into the compressing chamber and thence passes into a condenser, which consists of a rectangular chamber divided into two portions having a parallel series of pipes in each part. The nearest series of pipes to the compressing chamber through which the air first passes is surrounded by cold water, which is constantly running through it in an opposite direction to the current of air so as to cool the air passing through the pipes. The second series of pipes through which the air next passes is also surrounded by cold water supplied as we shall presently describe. The air having thus passed through these two series of pipes then enters the expansion chamber, where it is expanded and cooled, and then escapes through a temperature regulator of peculiar construction (acting in the same manner as a three-way cock or valve) into the refrigerator. In this refrigerator the vessels are situated which contain the liquid to be frozen, which may be in the form of pipes, through which the air, gas, or vapour to be cooled may be passed.

By means of the temperature regulator, a portion of the air proceeding from the expansion chamber may be admitted into the space surrounding the second series of pipes, so as to impart coldness to them. In fact, when the cold air admitted into the refrigerator has become heated, it passes through the same space but enters from another point on its way to the compressing chamber, and may previously to reaching the compressing chamber be made to pass through pipes surrounded by the running stream of water, which afterwards passes through the casing containing the first-mentioned series of pipes, and thus may have a cooling effect upon the water. Having thus circulated through the machine the same air is again admitted into the compressing chamber, and the whole operation is repeated, thus keeping up a complete circulation through the machine.

In order to maintain an equal pressure of air in the refrigerator and condenser a pressure regulator in the form of a balloon, made of elastic material, is in communication with the interior of the refrigerator. The regulator stretches out when the pressure in the refrigerator is greater than that of the atmosphere, and is contracted as soon as the pressure in the refrigerator is less than that of the atmosphere. The refrigerator is further provided with a valve opening inwards, which is acted upon by the atmosphere and supplies any loss of air in the machine, the fresh supply entering by the valve being dried by passing through chloride of lime previous to entering the machine.

Fig. 1 in our engraving is a side sectional view of the machine through the line from *a* to *b*. On fig. 2 is a plan with the refrigerator removed in order to show the cylinder and arrangement of pipes more clearly. A is the double acting cylinder, and B the piston of the same, which by means of the forked connecting rod C is connected to the crank D of the driving shaft which carries the fly wheel and revolves in one of its bearings on the pedestal E, which pedestal and the cylinder are fixed upon the cooler F. The cooler F consists of a rectangular enclosed chamber containing a series of parallel pipes. Situated on the top of the cylinder A, and partly supported by a pillar G, is fixed the refrigerator H. This is a

FREEZING AND ICE-MAKING MACHINE.

BY MR. FRANZ WINDHAUSEN.

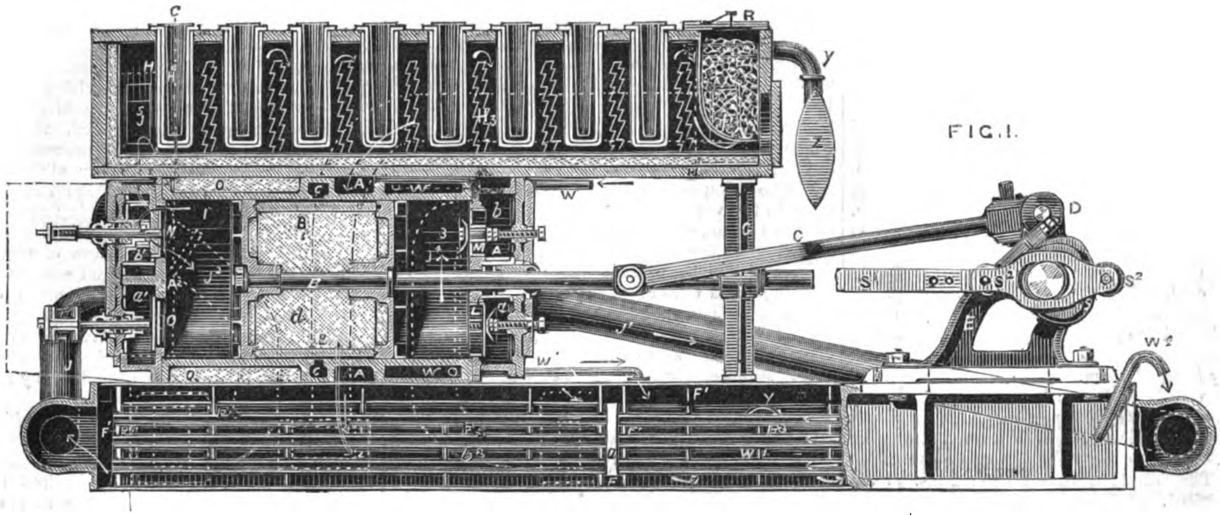


FIG. 1.

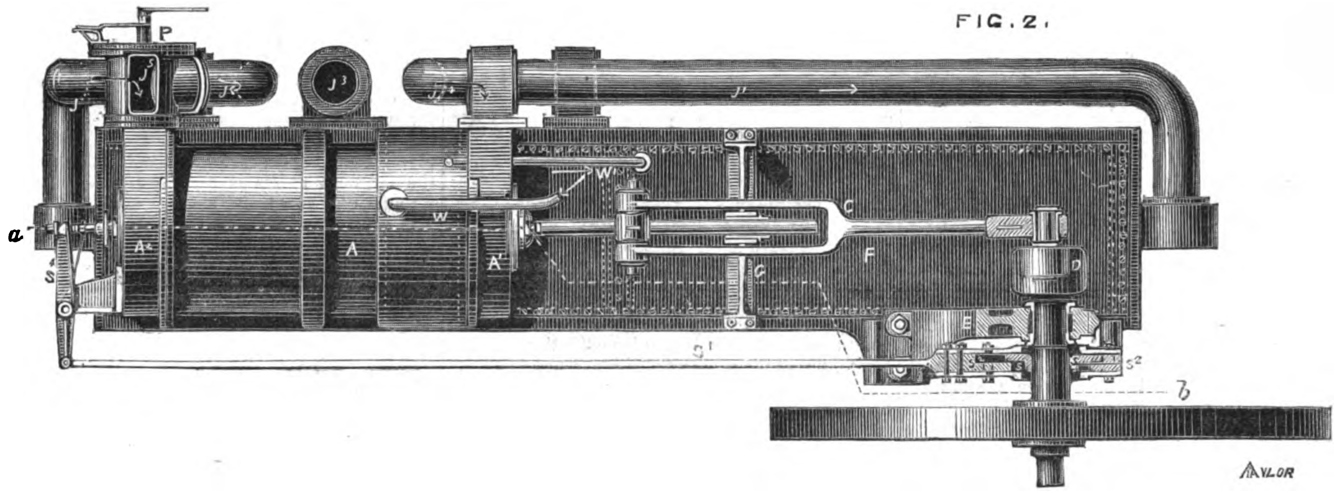

FIG. 2.

rectangular double-cased chamber, in which are suspended the cases H^1 and H^2 which contain the liquid or other medium to be cooled. All the internal parts of the machine communicate with each other by the pipes J^1 and J^2, and valves L, M, N, and O.

The cylinder A is fitted with covers A^1 and A^2, each of which covers is formed hollow and divided by a partition into two compartments a and b, and a^1 and b^1. These compartments communicate with the interior of the cylinder at their respective ends by passages fitted with valves; L being the outlet valve and M the inlet valve appertaining to the compartments a and b, and O being the outlet valve and N the inlet valve appertaining to the compartments a^1 and b^1. The front part of the cylinder in which the compression takes place is surrounded by a jacket W containing water to cool it, and the back part or other end of the cylinder in which the expansion takes place is enveloped in a bad conductor of heat Q^1 composed of sawdust or loose cotton, in order to prevent its being heated from the outside. e is an annular passage or space surrounding the cylinder and separating the front from the back part of the cylinder, in order to prevent the heat being carried from the front to the back. This space serves also as a receptacle for the grease to lubricate the piston. The piston B is nearly as thick as the whole length of the stroke of the crank D, and is constructed of two disc plates B^1 and B^2 fixed to the piston rod, and each of which plates is fitted with the ordinary cupped leathers. The intermediate space between the plates is filled with loose cotton and surrounded on the outside with a wooden casing B^3. This construction is designed to prevent the heat travelling from the front to the back part of the cylinder. The piston rod passes through a stuffing box and is guided at the same time through a bush fitted in the pillar G.

The actuating mechanism of the inlet and outlet valves N and O consists of two cams or tappet wheels S keyed upon the driving shaft, which alternately strike the friction or tappet rollers S_2 mounted upon the rod S^1 according to the expansion in the back part of the cylinder. The rod S^1 is connected to the forked lever S^4, the ends of which actuate the spindles of the valves O and N as illustrated in such a manner that the valve O allows the compressed air to enter the back part of the cylinder for a portion of the forward stroke of the piston, until the valve O closes, when the expansion takes place for the remaining portion of the stroke. During the back stroke of the piston the valve N is arranged to remain open by the disposition of the cams or tappet wheels S upon the driving shaft.

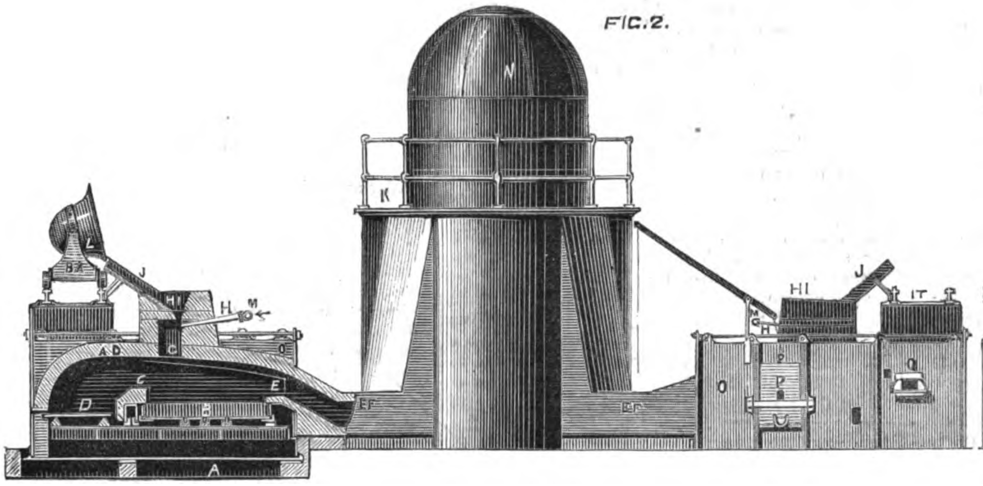
The cooler consists of a hollow enclosed chamber which at the same time constitutes the bed plate, upon which the cylinder A, pedestal E, and refrigerator F are fixed. Its interior is divided by the space E into two compartments w^1 and b^2 hermetically closed; in each of these compartments a series of parallel pipes F^2 and F^3 are fixed, being secured in the ends F^1. The interiors of these pipes are in communication with each other through the space a, and with the space a of the front cylinder cover through the pipe J^1, and with the space a^1 of the back cylinder cover through the pipe J. The space w^1 surrounding the outside of the first series of parallel pipes is entirely filled with a running stream of water, which flows away through the pipe W^2. The fresh supply, which is kept up by means of any ordinary pump, enters by the pipe W and passes through the jacket w surrounding the front part of the cylinder before it enters the space w^1 through the pipe W^1. In order to keep this water in direct contact with the outside of all the cooling pipes the metal plates F^4 are fixed in the compartment w^1 so as to compel the water to pass by or in contact with the outside of every pipe. By this means the water passes through in an opposite direction to the current of air which passes through the interior of the pipes and thus cools the air passing them to the lowest degree, with the smallest quantity of cooling water.

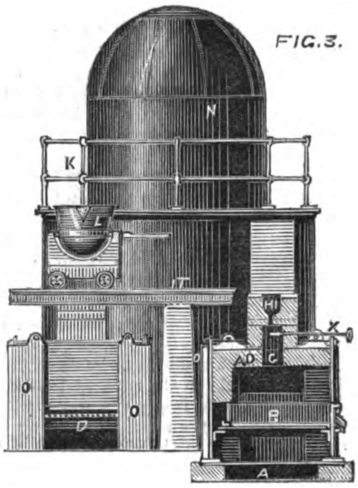
The other division of the cooler b^2 is similar to that just described, with this difference, that the pipes in this compartment are surrounded by a current of cold air instead of water. This air enters through the pipes J^2 direct from the compartment b^1 of the back cylinder cover, and also from the refrigerator F through the pipe J^3, and proceeds in the direction of the arrows 1 2 3 through the pipe J^4 to the compartment b by the front cylinder cover, where it is drawn through the inlet valve M by means of the piston into the front part of the cylinder, to be again compressed at the return stroke of the piston and afterwards driven into the cooling pipes through the outlet valve L and pipe J^1.

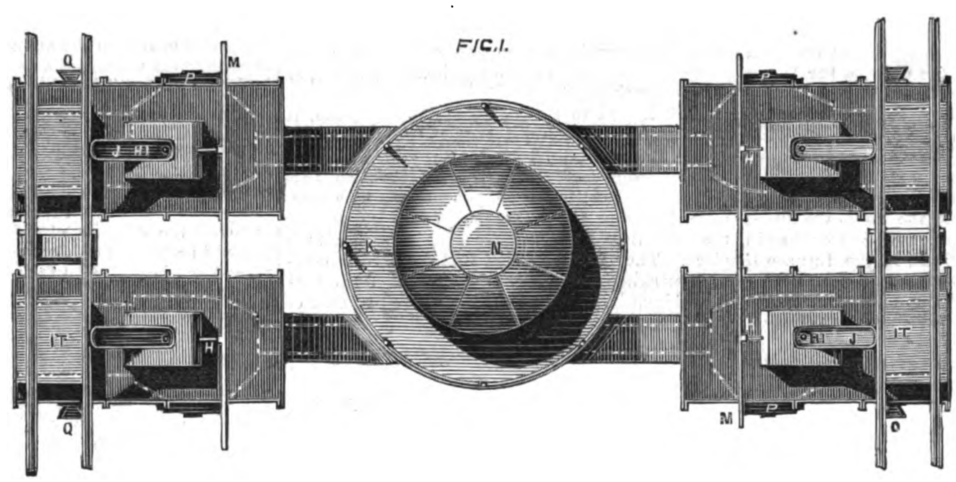
The refrigerator has already been described as being fixed upon the cylinder and pillar G, and consisting of a double-cased rectangular chamber H constructed of wood, the space between the casings being filled with a non-conductor of heat. The cover of this refrigerator has rectangular openings formed in it for the insertion of the corresponding rectangular metal cases H^1, which are open at the top and are suspended in the refrigerator in the same symmetrical order as illustrated. Inside these cases the ice-boxes H^2 (filled with water or other fluid to be frozen) are placed, and in order to effect an immediate contact between the two, the former H^1 are previously partly filled with a fluid which does not readily freeze (for instance spirits of wine), or at a higher temperature a solution of chloride of lime might be used. The cases H^1 may be employed themselves for freezing purposes by filling them direct with the fluid to be frozen, as they are loosely inserted in the openings formed in the cover to receive them and are packed under their top flanges with indiarubber or felt. To ensure a complete spreading of the current of air over the whole outer surface of the cases H_1 the zig-zag partitions H^3 are fixed inside the refrigerator between each of the metal cases, by which means a zig-zag course is given to the current. In the refrigerator the cold air expanded to atmospheric pressure enters through the pipe J^5, and in passing through imparts its cold to the chests H^1, and in a corresponding degree becomes

APPARATUS FOR THE MANUFACTURE OF IRON AND STEEL.

BY MESSRS. THOMAS, BACON, AND GROVES.







heated itself and finally escaping through the pipe J^3 into the cooler F.

In order to maintain one constant pressure inside the refrigerator its interior communicates through the pipe Y with an elastic ball Z formed of vulcanised indiarubber, which immediately becomes distended when the pressure is greater in the refrigerator than that of the atmosphere, and *vice versa.* Any loss of air inside the refrigerator caused by leakage of any of the parts is provided for by means of the valve R, which opens inwards by atmospheric pressure whenever the pressure inside the refrigerator is less than that of the atmosphere, thus allowing the deficiency to be made up, but before arriving inside the refrigerator such supply of air on its way passes through chloride of lime supported in a perforated tin box situated immediately below the valve R.

The refrigerator we have described is designed specially for freezing liquids; but for cooling air or gases, or condensing vapours, pipes are fixed in the refrigerator in the same manner as the pipes described in the cooler F, and which are surrounded with the current of cold air coming from the machine through the pipe J^3. Through these pipes the vapours to be cooled are conveyed in an opposite direction to the current of air passing outside them. In case the machine is required to cool and ventilate apartments, such as cellars, ship holds, hospitals, theatres, and other places, the cold air is conveyed from the tube J^5 directly into the places to be cooled, whilst fresh air is constantly supplied to the machine through a pipe in connection with the pipe J^4 to be thereby cooled and then forced into the apartment.

We have already described the particular manner in which the expanded air passes out of the back part of the cylinder from the compartment b^1 through the pipe J^3 into the condenser, and through the pipe J^5 into the refrigerator. It now, therefore, only remains to show more particularly how the cold air is divided so as to pass in the proper quantities through each of the pipes J^3 and J^5. For this purpose these pipes each open into a cylindrical compartment J^6, which is fitted with a segmental valve P, which turns with a hand lever, so that either of the mouths of the pipes J^2 and J^5 may be partially or entirely closed at pleasure by the hand of the attendant, and the exact relative sizes of such openings is indicated by a finger (forming part of the hand lever) upon a dial plate. Suppose the segmental valve P to be in such a position as that the mouths of the pipes J^3 and J^5 shall be to each other as 1 is to n, then, says Mr. Windhausen, a proportionate part of the expanded air is used for cooling the contents of the refrigerator and n parts are used for the first cooling of the compressed air. A simple calculation then shows that the compressed air is constantly being cooled to a lower temperature, and becoming in a corresponding manner colder by the process of expansion until it reaches the theoretical limit of n times as many degrees colder every time as the expanded air becomes according to the mechanical theory of heat. This maximum degree of cold, however, can only be effected under the supposition that the heat of the compressed air produced by the compression is entirely absorbed by the cooling water in the cooler, and that the heating of the air in the machine through the friction in the piston, the friction of the air in passing through the pipes, and the heat derived from without is not taken into consideration.

We may add that the agents in England for this invention are Messrs. Forbes, Born, and Co., of 2, South-place, Finsbury, and from whom we learn that one of these machines is now in course of erection at the Crystal Palace, where we hope soon to inspect it and to report upon its practical working.

It is stated that the growth and manufacture of sugar in the north of the colony of Queensland are proceeding with extraordinary rapidity and success, and there is every reasonable prospect that, in a very short time, Australian consumers will be entirely independent of foreign producers.

MANUFACTURE OF IRON AND STEEL.

An invention has been patented by Mr. J. Thomas, of Middlesborough-on-Tees, in conjunction with Mr. W. Bacon and Mr. H. Groves, which primarily consists of a new method of making refined iron, wrought iron, and also steel from melted metal run direct from the furnace. They refine the molten metal as it comes from the blast furnace; or the metal, if in pigs or cast scrap, may be melted in a cupola, air furnace, or any other furnace used for melting iron, and if the ground is practicable, they build the furnace at such a level that the metal may run direct from the blast or melting furnace into the air or refining furnace by gravitation, the refining furnace being near to the blast or melting furnace. The refining furnace has a high crown, and on the top of the crown is a well with one or more holes leading through the crown into the furnace. The furnace is heated up to the necessary heat for melting iron and fluxes, and the ores are first melted with the materials used for cleansing or improving iron. When the fluxes are properly melted the molten metal is poured into the well on the top of the crown and let run into the furnace through the holes.

About half way down the furnace are apertures opposite to the streams of falling metal, and into these apertures immediately under the falling metal are inserted paddles or flattened bars of iron, which are protected with a coating of fire-resisting material. The metal falling on the paddles is scattered into a very divided state, or the molten metal is scattered with a jet of air, steam, or gas, so arranged as to strike against the stream of falling metal as it enters the furnace. Previous to letting the metal into the furnace care is taken to have a good fire in the grate, the damper being opened at full so as to draw the gases through with rapidity, and, if the metal requires an excess of oxygen, holes are either opened near the bridge of the furnace to let in air, or superheated steam is introduced. The heated gases will have a powerful effect on the divided metal by attacking and burning out the impurities, while the liquid oxide or other fluxes in

the bottom will hold the dross given off from the metal. When the metal is all in the furnace under the slag, the paddles are drawn out, all holes stopped, and if necessary to make the metal more pure it is left to stand awhile, but with most metals it may be tapped out without loss of time if the operation has been properly performed, and refined iron will be the result.

In making wrought or malleable iron, the inventors tap and run the metal from the refinery furnace into a large ladle on a carriage, and if the puddling furnaces are higher than the ladle the metal carriage and ladle are raised up to a railway constructed on a level with the crown of the puddling furnace, on which is a well with a hole through the crown. The puddling furnace is fettled in the usual way and got up to a high heat, and the oxides or fluxes melted previous to charging the furnace with metal. Into the well on the top of the crown a sufficient quantity of metal for a puddling charge is then poured and let run down into the furnace. Through the side of the furnace is inserted a paddle similar to that used in refining, and the liquid metal is let fall on it so as to divide the metal; or the metal may be scattered with a blast of steam. As in the refinery process care is taken to have a good fire in the grate with a full open damper while the metal is running into the furnace, so that by the aid of the hot gases the iron may be further cleansed of its impurities. When the metal is all in the furnace the holes are closed and it is puddled in the usual way. When the iron in the puddling furnace is balled the balls are taken out, shingled, and rolled off into puddled bars. If bolts or bars are wanted, the puddled bar is run while hot on to a mandrel, and the doubled up iron hammered flat. These are inserted while hot into a re-heating furnace and when welding hot are drawn and rolled into the required size.

In making steel the melted metal is poured into a well on the crown of an air furnace as in refining; previously to pouring in the metal the fluxes are melted and the melted metal scattered as in refining. When the metal is all in the furnace if it is not properly refined it is run out into a ladle and poured into the well again on the top of the furnace, being run through and scattered as before. This scattering process is repeated as often as may be deemed necessary to burn out the impurities in the metal, and the gases are changed from carbonizing to oxidizing as may be required by regulating the fuel, the damper, and the gases to support combustion. The charge is then worked, wrought iron dissolved in the same, or more fluxes added as becomes necessary, and when the charge is ready it is tapped out and cast into the forms required.

It will be seen that in this process for making iron or steel the inventors begin with the molten metal and pass the product of each operation forward up to the finished bar of iron or of cast steel before letting it cool.

The accompanying engraving represents an arrangement of four puddling furnaces constructed according to this invention. Fig. 1 is a plan; fig. 2 a front elevation partly in section; and fig. 3 an end elevation also partly in section. A is the foundation and B the iron bottom of the same; C is the bridge; D the fire-place; A D the furnace crown; E neck leading to the flue E F; G the scattering chamber; H blast pipe for scattering, or, instead of a blast pipe, a paddle or flat bar as seen at X, fig. 3, may be employed for scattering. H I is the well or basin in the crown of the furnace, and having one or more holes leading down into the scattering chamber. This well receives the molten metal from a runner J leading from a ladle L; the ladle is mounted on a carriage B A, which travels on a railway I T. M M are air or steam pipes for supplying the blast pipe H; N is a boiler in the middle of the four furnaces, and K is a staging round the boiler. O O are binding plates for the furnaces; P P are the charging doors, and Q Q the fire holes.

THE Argentine Republic has issued a circular calling attention to a Grand Exhibition to be held at the city of Cordova on April 17, 1870. On the same day will be celebrated the completion of the Central Argentine Railway between Rosario and Cordova, whereby the two cities, heretofore separated by five days of fatiguing stage riding, will be placed at a distance of a few hours' travel, and, by means of the telegraph, in instantaneous communication. The managers invite the exhibition of machines for the manufacture of woven stuffs, paper, sugar, and alcohol, agricultural implements, particularly those of a labour-saving character, steam engines, models and plans of bridges, and whatever may help to improve agriculture, mining, and modes of communication.

THE DANGER OF PLAIN CYLINDRICAL, EXTERNALLY-FIRED BOILERS.

THE Manchester Steam Users' Association has for years laboured to call steam users' attention to the danger of external firing and to the treachery of the plain cylindrical colliery boiler, and the following explosion is an illustration of the correctness of this view. The explosion occurred at a colliery on the afternoon of Thursday, October 14, and resulted in the death of two men as well as in injury to one other. The boiler was of the plain cylindrical, egg-ended, externally-fired class, with the plates laid longitudinally, so that the seams of rivets ran in line from one end of the boiler to the other. It was about 30ft. in length by 6ft. in diameter, while the thickness of the plates was ⅜in. and the pressure to which the safety-valves were loaded about 35lb. per square inch. The boiler gave way at the bottom over the fire, rending in a somewhat zig-zag course throughout its entire length from the front to the back, when the cylindrical portion of the shell opened out and tore away from the two hemispherical ends, the parts being thrown to considerable distances, and the pipes and ruins of the seating scattered right and left. Added to this, a stonemason lighting his pipe at the fire door was killed on the spot, and two other workmen struck by the falling debris and seriously injured, one of them dying shortly after, while, in illustration of the force with which some of the fragments were thrown, it may be stated that a horse standing in a butcher's cart some thirty yards off was struck down and instantly killed, as if by a cannon ball.

With regard to the cause of the explosion, it was stated at the inquest that the boiler, though only a little more than three years old, had been under repair several times, and that two new plates had but just been put in over the fire, while it was as the steam was being got up for the first time after this that the explosion took place. The engineer stated that though the ordinary working pressure was about 35lb., yet that it could not have exceeded 24lb. at the moment of explosion, while he was confident that the plates put into the boiler were of first-rate quality, so that "it was a mystery to him why the boiler burst, as he considered it ought to have stood a pressure of 300lb. on the square inch." The foreman smith said he was "beat entirely in endeavouring to account for the explosion." To this the coroner added that "the Government Inspector of Mines had made an investigation, but admitted that he had no light to throw on the subject, and therefore it was apparent that the occurrence was shrouded in the greatest mystery." The jury, without requiring further evidence, found that "the deceased was killed by a boiler explosion, but how the catastrophe originated there were no means of ascertaining."

In this case the inquest was conducted with considerable despatch, being held the day but one after the catastrophe, so that it was concluded on the same day that the report of the occurrence reached Manchester. On the Association's Inspector reaching the scene of the disaster, he found that the boiler had been cut up and thrown on the scrap heap the day after the inquest was held, so that those who had charge of the boiler seemed resolved that if they could not arrive at the cause of the explosion themselves, nobody else should do so. The colliery engineer, who could have given the Inspector some information as to the direction of the rents and flight of the parts, was most uncommunicative, and referred him to the scrap heap for information, and to the record of the inquest in the local newspaper, so that but few particulars could be obtained. After the Association had gone to the expense of sending an officer between 100 and 200 miles, in order to throw light on the cause of a fatal steam boiler explosion, and thus to save human life, this reception was rather discouraging, though by no means singular. The facts of the case, however, speak for themselves. Here was a boiler but three years old, which had just been repaired and turned out as sound, yet, on the first time of getting up steam, and before the pressure had exceeded 24lb., it exploded, while all connected with it considered the occurrence as an impenetrable mystery. Such boilers certainly deserve the character the Association has given them, viz., that of being untrustworthy and treacherous. This explosion, in common with many others, resulted from the simplest causes, and might have been prevented by the exercise of common knowledge and common care.

UTILISING AMMONIACAL SKIMMINGS.

AMMONIACAL skimmings is a bye-product of the manufacture of galvanised iron, consisting principally of a mixture of chloride of zinc, oxychloride of zinc, oxide of zinc, metallic zinc, and chloride of ammonium. Hitherto it has been customary to convert this material into zinc oxide by calcination, which mode of treatment occasions the loss of the zinc existing as chloride, and part of the zinc existing as oxychloride, and also of the chloride of ammonium. In order to avoid this loss and to recover the ammonia from the chloride of ammonium, Mr. John Pattinson, of Newcastle-on-Tyne, has patented an improved method of treating the skimmings. He reduces them to powder and mixes with it sufficient powdered lime or other suitable alkaline earth to decompose the chloride of zinc, oxychloride of zinc, and chloride of ammonium. As the skimmings are of variable composition it is necessary first to ascertain the amount of chlorine contained in that to be brought under treatment in order to determine what proportion of lime is required for the decomposition of the chlorides and oxychloride. For every thirty-five parts of chlorine contained therein about twenty-eight parts of unslaked lime, or about thirty-seven parts of slaked lime, should be provided and mixed with the skimming. A suitable charge of this mixture is put into a retort, and heat applied thereto so as to decompose the chloride of zinc, oxychloride of zinc, and chloride of ammonium.

By this operation the ammonia contained in the skimmings is volatilised as ammoniacal gas. If it be intended to utilise this gas the aperture of the retort must communicate by pipes with vessels for condensing the ammonia in water so as to form liquid ammonia. Or the ammonia may be made to combine with acid so as to form sulphate of ammonia or other ammoniacal salt. When treating the skimmings with the view to collecting the ammonia the mixture of skimmings and lime is placed in a retort (which may be similar to a gas retort) and heated until the evolution of ammonia has ceased. A temperature somewhat below a dull red heat is generally sufficient to effect the necessary decomposition. After this treatment the charge is withdrawn from the retort and is lixiviated with water, so as to dissolve out the chloride of calcium or other alkaline earth chloride formed during the subjection of the mixture to heat. The washed residue, which contains all the zinc of the sal ammoniac skimmings under treatment in the state of oxide, may then be dried and zinc extracted from it by smelting in the usual manner.

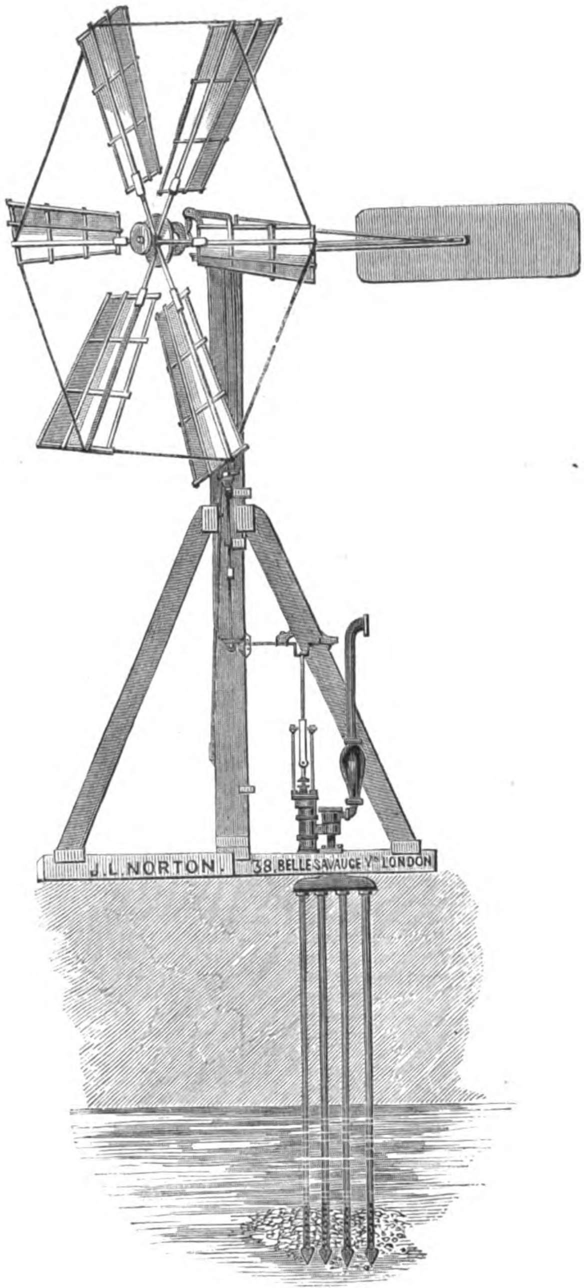
VEGETABLE MANURE.

LET Liebig be comforted. We may yet restore to our soil, and from an unexpected quarter, the annual waste of certain elements of their fertility. In the Atlantic Ocean, west of the Azores, there exists an area seven times larger than all Germany, according to Humboldt, completely covered with a dense mass of vegetation. This vast floating jungle is called the Saragossa sea, and a M. J. Laviniere has calculated that it yearly produces enough vegetable matter to manure no less than 1,800,000,000 acres! The "Journal" of the Chamber of Agriculture asks, can these prodigious marine prairies and savannahs be utilised for the replenishment of our impoverishing husbandry? This French gentleman, with an original idea, has proposed to his agricultural society that the ships which are now occupied during the summer in cod-fishing shall, in other seasons, be employed in ploughing into the thick mass of seaweeds, and loading with cargoes for the Azores, where the vegetable matter can be dried and pressed, and, after having valuable salts extracted from it, can be conveyed as a condensed manure to Europe or anywhere else. Such is the scheme, but many considerations have to be satisfied before that wet salt weed is profitably brought into competition with our highly-concentrated bird-dung, blood, and mineral manures, and Mr. Lawes, Mr. Odams, and their brother manufacturers will prosper some time before they are driven out of the market by M. Laviniere.

A LETTER from Oran states that the sea-wall of that port, for a length of 800 metres, was completely destroyed the week before last by an immense tidal wave. The Mediterranean had been raging with great violence during the preceding night, and at about eleven in the morning a first breach, 40ft. wide, was made, and from that moment the wall rapidly broke up, the immense blocks of stone being swept away like cardboard boxes. The spray from some of the waves reached a height of more than 100 yards. Many vessels were for a time in great danger, but were at length moored to a place of safety.

SELF-REGULATING WIND ENGINE.

BY MR. J. L. NORTON.



SELF-REGULATING WIND ENGINE.

UPON a recent visit to the wharf of Messrs. Owens and Co., of Whitefriars, to inspect some hydraulic machinery—of which we shall have something to say in a future number—we found the self-regulating wind engine illustrated in the annexed engraving. It has been made for Mr. J. L. Norton, who is now largely using them for working his tube wells, for which purpose they answer admirably. The wind engine under notice was one of several which were about to be sent to Austria. It is illustrated as fitted to Norton's pump, which is drawing supplies from a set of tube wells. Its construction is very simple, and its action continuous so long as there is wind enough to fill the sails, and it does not require much. One advantage is that it will work night and day without any watching. The sails regulate themselves according to the wind. It can be managed by a labourer, is stopped instantly, and the power can be varied as required. The first cost is the only one; it costs nothing to keep it in repair, where other motive power requires constant attention.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending November 20, was 1,776. Total number since the opening of the Museum, free daily (May 12, 1858), 1,682,068.

RAILWAY CARRIAGE DOOR.

THE frequent cases of injury to the fingers of railway passengers by the hasty closing or rather banging to of the doors of carriages in these days of rapid transit, is an evil which has been dealt with by Mr. R. Wright, of Richmond, Yorkshire, in a recently patented invention. To prevent injuries to fingers by the closing of the doors, in place of supporting the doors on hinges, as hitherto, Mr. Wright supports it on two pins, one at the top and the other at the bottom, and the side edge of the door near to which the pins are placed is made hemispherical, so that when a door is opened this edge is always close up to the door post, so leaving no opening for the people's clothes or fingers to get between them. The opposite edge of the door is provided with a yielding edge to prevent any injuries to fingers if this edge of the door is closed upon them.

In the annexed cut we have shown a railway door constructed according to this invention. Fig. 1 is a side view of the door, and fig. 2 a horizontal section on the line 1 1, fig. 1. *a a* are the pins at the top and bottom of the door, and upon which the door swings. These pins, as shown at fig. 2, are connected with the hemispherical edge of the door, which fits in a corresponding recess in the door post, so that when the door is open this eged is always close up to the door post. The opposite edge of the door is, in the door shown in the engraving, made capable of yielding by turning on pivots or hinges should it as the door is closed come into contact with anything between it and the door post. The horizontal rails *b b* at the top and bottom of the door are of

FIG.1.

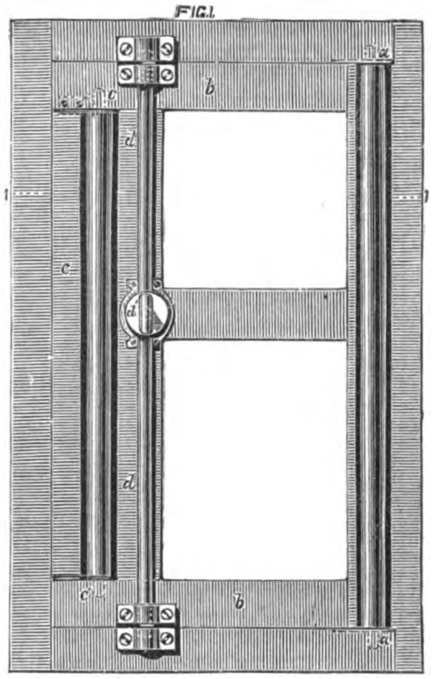


FIG.2.

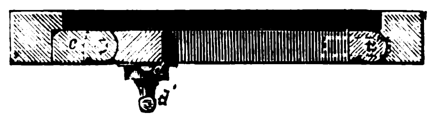

the usual length, so that they shall catch against the door frame and prevent the train turning inwards. *c* is the yielding edge, capable of turning on pins or pivots c^1 in a similar manner to the door. To fasten the door bolts such as shown at *d d* are used, and which can be simultaneously withdrawn by turning the handle d^1.

CIVIL AND MECHANICAL ENGINEERS SOCIETY.

THE opening meeting of the eleventh session of the above society was held at the Whittington Club on Wednesday evening, October 27. After some observations on the progress of this society, which has been in existence for ten years, the President proceeded to make the following remarks:—Referring to topics of general interest, I purpose, in the first place, to notice briefly the City improvements. Two great works which have been in progress for years past are now virtually complete. In a few days Blackfriars Bridge and the Holborn Viaduct—the latter already accessible to foot passengers—will be formally opened. These, and other works now in course of construction, vast in themselves, are but an instalment of what is required. New and appropriate thoroughfares are urgently demanded for our gigantic traffic, and must sooner or later be made. An able report on this subject has been drawn up by Mr. Haywood, engineer to the Commissioners of Sewers, who has attentively considered not only the wants of to-day but the prospective requirements for the next forty years. The following are his chief recommendations as to the most effective means of relieving the principal traffic arteries of our great city:—

The great streams of traffic which are from north to south pass over London, Southwark, and Blackfriars Bridges, and as these are insufficient a new bridge, with suitable approaches, in the vicinity of the Tower is absolutely necessary. A good approach on the north side could be made without much difficulty by improving thoroughfares already existing. On the south side, however, new approaches would be necessary, and these should extend to Bermondsey-street, and be carried on to Great Dover-street by the Old Kent-road, and, perhaps, on to Camberwell Green. I may notice that the position of London Bridge, in relation to the immense districts lying far to the eastward on both sides of the river, between which it forms the means of communication, is a strong argument in favour of this bold scheme. While admitting that a considerable increase of facility for the passage of its great traffic would result from the widening of the present bridge, Mr. Haywood is of opinion that the construction of the new bridge he advocates is the only true solution of the problem. He takes this opportunity of protesting energetically against the very barbaric proposition that an increase of car-

riage way could be obtained on London Bridge by appropriating for that purpose the present footpaths, which are to be replaced by attaching iron cantilevers for the support of new ones. But it is incredible that anyone could seriously advance such an outrageous plan for the gross disfigurement of one of the most beautiful bridges in the world. By the formation of the thoroughfares in the district of Bermondsey, as recommended by Mr. Haywood, and the construction of the bridge at the Tower, a line of direct communication would be afforded between this part of London and Shoreditch, and much traffic would cross the bridge. In the course of these improvements it is suggested that Billingsgate Market be removed from the present very inadequate building to a site lower down the river or to Farringdon-street. To accommodate shipping a central span of the bridge could be made to open to admit of vessels passing up and down the river. As an alternative, a tunnel is suggested, although not so convenient, and in addition steam ferries might be established at various points. In respect to the east and west traffic, coming to the City by the lines of Oxford-street and Holborn, Piccadilly and the Strand, the whole line from Temple Bar to Cheapside is quite insufficient, notwithstanding the relief afforded by way of Cannon-street, while the junction in the heart of the City of both lines of road causes a jamb which can only be relieved by two new broad thoroughfares between the districts lying east and west of the City. While the noble lines of the Thames Embankment fitly stand for one of these, a new east and west street will be requisite for a breadth of 70ft. or 80ft. It is proposed that this broad line of road shall commence at the east end of Holborn Viaduct and extend to Whitechapel, High-street, close to Commercial-street. From Newgate-street it would pass eastwards across King Edward-street and St. Martin's-le-Grand to the north of the Post Office, thence across Noble-street, Wood-street, Aldermanbury, Basinghall-street, to the north of the Guildhall and Coleman-street, to a point about 250yds. north of the Bank. Thence it would cross Little Bell-alley and be carried on to the end of Bloomsfield-street, and by way of London-wall and Wormwood-street to Bishopsgate-street, and finally across Houndsditch and Petticoat-lane to its junction with High-street, Whitechapel. Opposite this point will commence the new street, projected by the Board of Works, from Whitechapel to the Commercial-road. This new road would take the largest portion of the north-west and north-east traffic, which now passes right through the centre of the City, and would furnish additional outlets to Aldersgate-street, Noble-street, Wood-street, Aldermanbury, Basinghall-street, and Coleman-street, rendering any widening of these unnecessary, and relieve the lines of Gresham-street and of London-wall, Wormwood-street, and Houndsditch. It would form in addition an easy means for traffic reaching all the stations of the Great Northern Railways. The formation of this great thoroughfare would necessitate the removal of Christ's Hospital and the Money Order Office in St. Martin's-le-Grand, which, however, would be a matter of very minor importance compared to the demolition of the fine old training college of blue coat celebrity. Many lesser improvements are recommended, and valuable suggestions offered as to river traffic bridges and subways across public thoroughfares, also police regulations, and altogether the report is at once valuable and interesting.

This year will certainly be famous in the civic annals as one in which some of the most important of this century's City improvements have been completed, and how successfully the objects intended have been accomplished is apparent to everyone. The Holborn Viaduct, of which any Ædile might be proud, will, in a few days, be thrown unreservedly open to public traffic. As we have paid several visits to this grand work when in progress, and passed through its well-built and spacious subways, each can estimate for himself how thoroughly everything has been provided for, and how solid is the entire structure. When we contrast the broad level plateau that now meets the eye with the steep descent of Holborn-hill, the muddy or dusty crossing of Farringdon-street, on the other side the corresponding climb up to St. Sepulchre's Church, and, finally, the very unpleasant proximity of Newgate-street, with a dead meat market, and the contact of its wares with the shoulders, we have every cause to congratulate ourselves on the change. And now that all these have gone away among the traditions of London, we can only wonder that this state of things was suffered to endure so long. When Newgate-street has been widened through its entire length, the full benefit of this improved termination of the long line of Oxford-street and Holborn will not even yet be reaped. For not until some continuation of this great artery into remote Whitechapel, such as that proposed by Mr. Haywood, be carried out, will this great east and west thoroughfare have reached its natural and necessary limits.

Besides the two noble works now completed, the last portion of the Thames Embankment has made good progress, and the new street, which forms the junction of our magnificent water-side boulevard with the heart of the City, is also in a forward state, one portion being used for general traffic. The fine effect of the space opened up beside the civic palace by Mansion House-street naturally suggests very forcibly the often repeated query "why not demolish the block of buildings between the Poultry and Bucklersbury, and widen this narrow street, which strangulates the traffic passing east and west by way of Cheapside?" The miserably defective accommodation afforded by this contracted roadway, and the insufficiency of the cramped footpaths for the stream of passengers which flow uninterruptedly all day long, become more apparent every year. It is now high time that the precedent of Middle-row, Holborn, be extended to this obstruction, and a city so wealthy as our Babylon, and seemingly zealous in effecting necessary improvements, will, doubtless, include this also among their number, even at some cost.

Associated with City improvements is the Metropolitan District Railway. It is difficult to foresee what may be the result of the present agitation; whether the extension to the Mansion House be carried out or not, it is not at all probable that Parliament would sanction the abandonment of the line on to Tower-hill. A rumour is afloat that an attempt will be made by the London, Chatham, and Dover Railway, or the directors, to obtain powers for a new station, close to Holborn Viaduct, to replace the present inconvenient one at Ludgate-hill. For this purpose, it is proposed that the sum of £100,000 or thereabout, which the Government will pay for the company's telegraph, be appropriated, but as the moneys must in the first instance be paid over to the arbitrators, these gentlemen may naturally employ these funds for the reduction of the debt on capital account. From this source, the construction of these telegraphs was defrayed, so that in all probability the new station must wait for better times ere it becomes an accomplished fact. The East London Railway works have rendered necessary the final closing for foot traffic of the Thames Tunnel, which has been open for over twenty-six years. Though at best a dingy and depressing subway, it long held a foremost place among the sights of the metropolis, and indeed the many difficulties which had to be encountered in its construction, and the skill and patience brought to bear by its famous originator, have placed it high in the archives of engineering enterprise. Though on the north side some time must elapse before this line of railway, projected in 1863 by the late Mr. J. S. Burke, and authorised by Parliament in 1865, can be completed, the directors have given notice to the Board of Trade that the first section would be ready for inspection after the 15th inst.

Turning from *terra firma* to the great water highway in our midst, we have also to note good progress in the new great works which line its borders and span its current, with the single exception of the unlucky pneumatic tube at Whitehall—commencing from the west. Foremost among these is the southern embankment, which has been carried to its proposed limits; and now from Westminster Bridge a magnificent promenade, carried past the palace of the Primate and the historic Lollard's Tower, replaces the old net-work of dangerous slums. Here, too, is rapidly rising the handsome pile of the new hospital, which has been admirably arranged to prevent contagion spreading its subtle poison over the whole infirmary. By separating the buildings into many blocks quite apart from each other, infectious diseases are localised and confined to their narrowest limits, as far as skill and foresight can bind them. At the same time the outward effect of one grand structure is maintained. On the north side the embankment makes rapid progress towards completion. From Westminster to the heart of the City we shall soon have an unequalled thoroughfare, which will do much to relieve the crowded line of the Strand, Fleet-street, and Cheapside. Æsthetically viewed, the architectural features of the engineer's design cannot be found wanting in mass, in outlines, appropriate detail, or severe general beauty.

Spanning the river where the embankment ends, Blackfriars Bridge now begins to strike the eye in all its completeness, but until the temporary wooden substitute (a work itself of much engineering skill) be removed, we can scarcely judge how far the adjacent railway straight lattice girders will interfere with the effect of Mr. Cubitt's handsome structure. When contrasted with its gloomy neighbour of Southwark, Blackfriars Bridge is a standing proof of the advance which has been made in the decorative section of engineering art. The older bridge was the solution of a problem unattempted before its time, and, with one exception, its construction is perfect so far as the disposition of the metal in the arches is concerned. But everyone must feel that the general effect, if massive, is sombre, and in no way improved by the dingy shade of colour employed. In neither case is the constructive material in any way disguised, nor is it desirable in similar cases that any attempt should be made to give a false appearance of stone to an iron bridge. This has been done, it is true, in the very beautiful structure at Westminster to some extent, but here it was requisite that some harmony should be produced between the elaborate and florid style of the senatorial palace and the broad bridge at its doors. The present generation has produced no architecture as well as no poetry of the period, that is, no style which will in after ages be distinguished as English of the 19th century. It is expedient, therefore, to adopt a safe model in its entirety, and to adapt a pure style to the specific requirements of the moment. Ornate Gothic having been chosen for the Houses of Parliament, to have placed a strong palpable iron bridge of the present day in close propinquity to an imposing building designed in a style that carries the mind back a great while, would by the fitness of things have been a hideous anachronism. Blackfriars Bridge is not intimately connected with any such surroundings, and we can bring an independent judgment to admire the just taste of its outlines and details. Here again at top the piers, the granite pillars, eminently handsome in themselves, harmonise with the iron arches, but the capitals, exceedingly beautiful and delicately sculptured, seem at present somewhat too glaring. This time and our smoke will remove, and when statues in bronze come to form the surmounting finish, these capitals will be further toned down.

As we may expect that Mr. Haywood's bold scheme of a new bridge near the Tower will not be entertained otherwise than an improvement of the future, the question of dealing with London Bridge demands immediate and serious consideration. The hideous tinkering of iron cantilevers I have referred to is in no case admissible, though of what civic wisdom may be capable it is difficult to foresee. But, however effected, the enlargement of London Bridge is extremely desirable, that is, assuming, as we may do, the postponement of the greater project. This very necessary addition to the present width must not entail any disfigurement of the beautiful contours, but must harmonise with the graceful structure which was opened about thirty years ago. Lower down the river we come to a new means of communication between the busy districts on either bank, in the Tower Subway. Mr. Barlow's clever little underground passage—clever both in design and execution—makes rapid way, and, in addition, what is so important in every work of this nature, it promises to be a complete commercial success. Its cost of construction has been small, and its position ensures much traffic; hence the desired result, good dividends, may be confidently expected.

Before leaving the river there is another point I wish to refer to. It is obvious to all that many admirable sites are available on the embankment for magnificent buildings. This session was re-opened the question of where our new Palace of Justice should be located. Sir Charles Trevelyan's scheme, oriental in its magnificence, was much too costly to be entertained, but besides this extensive design the Chancellor of the Exchequer puts forth a more subdued plan for placing the new Law Courts between Howard-street and the embankment. Sir Roundell Palmer, however, opposed in the strongest terms the alteration of the determination already come to by Parliament, and we may anticipate a keen debate when the report drawn up by Mr. Lowe and Mr. Layard is laid before the House of Commons. Coming from such a source as the thrifty guardian of the national purse, we need not be anxious about reckless expenditure being requisite to give effect to his plan. In no case can we expect, if we deem it necessary to resell the ground already cleared for the Carey-street site, that we shall escape without loss. This, however, should scarcely be suffered to stand in the way of an important embellishment of our noble river. While the æsthetic phase of the question justly holds an important place in its consideration, the convenience of all interested is of the primary consequence. As for the lawyers, the foremost of them, Sir Roundell Palmer, strenuously upholds the original site as in every way most convenient for himself and his brethren of the wig and gown; and certainly the present position of the legal colonies favours this view of the case. As to the expense, Mr. Lowe puts the acquisition of the Howard-street site, together with the buildings he proposes to erect—in fact the law courts complete—at £1,600,000, but it is probable this sum will be considerably exceeded. If economy is of more moment than a stately pile which shall be worthy of its prominent site, a river frontage will expose any deficiency for which a straitened expenditure may be responsible. As to Carey-street, according to Mr. Lowe's estimate, £600,000 are necessary before the requisite additional ground be acquired, which, with a nice little extra figure of £400,000 for approaches, makes another million, and this, with £780,000 already expended, amounts to one and three quarter millions that must be spent without taking into account the erection of the buildings themselves. Putting out of question the most important division, of which lawyers are the best judges, it will be necessary to see the plan Mr. Lowe proposes for his buildings before we can judge if the embankment is a more judicious location than the other. If, in fine, more money could be devoted to this object, and the legal opposition cease, there is no question as to the fitness of the noble site on the embankment to grace a noble judicial palace, which should be the admiration of the thousands who will pass daily both along the thoroughfare at its base and on the river. We must, then, be content to wait till we know fully

what Mr. Lowe's plans are before we pronounce finally on "the battle of the sites."

A much more vital question is the water supply of our city. Agitation culminated in a special commission, who have taken evidence, medical and scientific, on the subject. The former goes to prove that there is no reason to regard the Thames water as injurious to health when proper care is taken in the matter of filtration, and the following are the conclusions of the committee:—While they consider Mr. Bateman's scheme. in an engineering point of view, as the most feasible and practicable, they are of opinion that as to quantity and quality the waters of the Thames and Lea, supplemented by what will be retained by works for storing up the flood waters of those rivers, will be amply sufficient for the present and prospective wants of the metropolis. It is strongly recommended that the existing works of the water companies be purchased, and that the necessary extensions to these be carried out by a responsible body who shall have the entire management of the water supply. To meet the charge of all this it is proposed that two rates be levied, one a domestic and special rate on all dwelling-houses, the other a public or general rate on all rateable property. A plan similar to this has been in operation in Manchester and Glasgow, and has worked very well.

(To be continued.)

THE OUDH CANAL.

THE Government of India has just issued orders approving the designs of Captain J. G. Forbes, R.E., for a canal project in Oudh and the adjoining districts, much larger than that of the Ganges canal. The river Sardah flows from Nepaul into Oudh through the malarious jungle caused by the drainage of the Himalayas. From that river water is to be taken off sufficient to irrigate 19,000 square miles between the Sardah and the Gogra on one side and the Deoha and Ganges on the other. Colonel Anderson, the Inspector-General of Irrigation, states that the cutting of the first 12 miles will cost half a million sterling and will be of greater magnitude than any yet carried out in India. The "Times" gives the following particulars of this undertaking:—The dam is to be made at Bumbassa, the canal head at Nuglah, 8 miles lower. A supply of 13,000 cubic feet a second is required, and if the Sardah cannot give this at Bumbassa and Maggaen, lower down, the Korreallie river will help. The main canal will run through Oudh for 80 miles, and then bifurcate into the Benares canal, 280 miles long, and the Jounpore canal, 235 miles. But the project embraces the western districts also. The whole is estimated to cost close on five millions sterling, and a return of 11 per cent. is estimated, after paying 4 per cent. charges. This is to be got, however, only by enforcing the severe provisions of Colonel Strachey's Bill, or charging the proprietors of irrigable but not actually irrigated lands 5½d. per acre. As so much of the canal will pass through Oudh, which has an abundant water supply from wells and marshes, Colonel Anderson takes a much less sanguine view of its prospects, nor does he expect the Oudh Talookdars or their tenants to take the water unless exceptionally low rates are imposed. The surveys for the proposed canal from Ragmahal to Calcutta are going on, and that land is being taken up for the canal from the Damooda at Raneegunge to Serampore or Howrah, on the south side of the Ganges and Hooghly. The line of canal in Sirhind, too, running chiefly through the Native States of Putiala and Nabha, is being surveyed. The cutting down of the expenditure on ordinary public works by so much as 1¼ million sterling a year will set engineers free for State railways and canals.

LOSSES IN ACTION.

AN article in the last number of the "Preussische Jahrbucher" draws an interesting comparison between the losses of the rival armies in the battle of Koniggratz and those sustained at the other principal battles of the last two centuries. It appears that the Prussians lost at Koniggratz, in dead, wounded, and missing, 359 officers, and 8,794 men, and the Austrians 1,147 officers, and 30,224 men. The proportion of the losses to the total force engaged on each side was, for the Prussians, 1-23rd; for the Austrians, 1-7th; for both together, 1-11th. In the battle of Malplaquet (1709), the proportion of losses was 1-5th; at Rossbach (1757), 1-25th; at Leuthen (1758), 1-11th; at Zorndorf (1758), 3-8ths; at Austerlitz (1805), 1-4th; at Eylau (1807), 1-4th; at Wagram (1809), 1-8th; at Borodino (1812), 1-3rd; at Leipsic (1813), 1-5th; at Belle Alliance (1815), 1-3rd; at Solferino (1859), 1-8th. The three greatest of the above battles, the article proceeds, are those of Leipsic, Koniggratz, and Wagram, at which the total number of troops engaged was 460,000, 430,000, and 320,000 respectively. The three bloodiest were Leipsic (90,000 men lost), Borodino (loss 74,000), and Belle Alliance (loss 61,000).

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, November 25.)

SINCE our last report the business transacted in chemicals has been of a very satisfactory nature, principally for home consumption, the majority of the large buyers having taken advantage of the present low prices in the staple articles to secure sufficient for their requirements during the ensuing year. The reduction in pyrites has created a more lively feeling amongst the alkali makers, and it will doubtless again have the tendency to stimulate them to an unnecessarily increased production. In minerals of all descriptions the amount of business negotiated during the past week has been unusually large, exclusive of the public sales, but more especially in lead, zinc, and copper ores, the standard of the latter having slightly advanced. In metals there is little of importance to report. A considerable amount of business has been done in pig iron during the week, and prices close very firm and steady. Manufactured iron quiet, buyers not having yet realised the advance. Copper is in moderate demand, and smelters are firm at present prices. Tin and spelter are at nominal values, with an average business. Lead is selling freely, and present prices are readily obtainable. Soda: large contracts have been concluded in soda ash and caustic soda for 1870 consumption, at present low rates, of from £7 to £7 5s. per ton for 48 Ash; and £13 to £13 5s. caustic at 60. Crystals have also met with heavy sales, at £3 15s. to £3 17s. 6d. Bi-carbonate more in request at £9 10s. Nitrate of soda: fluctuates between 15s. 6d. to 16s. Potash: muriates being still scarce command £7 5s. to £7 7s. 6d. for 80. Saltpetre: not much selling, at 23s. for Calcutta, and 27s. for English refined. Alum: having been well sold forward, is pretty firm at late quotations. Ammonia: sulphate remains steady at last week's prices, £17 to £17 10s. for best white, and £16 to £17 for grey. Copperas: somewhat more activity displayed in green and rusty, at 52s. Dry is in continued active request at 50s. Pyrites: for present consumption prices remain at previous quotations, but, for spring delivery, contracts have been entered into on easier terms. Lime: phosphates are more inquired for at 52s. 6d. for 65. Bleaching powder at £8 for contracts to £8 5s. for 35. Disinfectants, at 5s. 8d. per cwt. for firsts, meet with considerable favour. Manganese: rather under average sales, at 95s. for 70. Guano: Peruvian quiet, at £12 10s.

METALS.—Iron: Scotch pigs firm at 54s. 8d. to 54s. 9d. Cleveland quoted from 45s. to 45s. 6d. for forge, and 50s. for No. 1. Welsh bars, £6 10s. to £6 15s.; Staffordshire, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: English tough, £72 to £73; Chili slab, £68. Tin: prices are quite nominal, English ingots being quoted at from £120 to £123; Straits, £117 10s. to £119. Lead: firm. P.G. best English soft pig lead, £19. Spelter: not much doing. Silesian, special brands, £19 10s. to £19 15s.; English, £20 10s.; hard spelter, for export, £16 10s.

Legal Intelligence.

VICE CHANCELLOR'S COURT,
NOVEMBER 18.
(Before Sir W. M. JAMES.)
SALOM v. JASSMAN.

THIS was a motion for an injunction to restrain the defendant, who is a saddler in North Audley-street, from making and selling any horse clippers in infringement of a patent granted to the plaintiff, an optician in Regent-street, in March, 1868. The plaintiff's invention is a two-handled instrument formed of a knife or cutting plate of metal, fixed to a plate of metal edged like a comb, and constructed so that the knife in passing over the comb plate cuts off the hair. The defendant sells a similar instrument, made under a patent invented by a Mr. Rawlings, and sold as Rawlings's patent horse clipper. The defendant denies the validity of the plaintiff's patent, and says that it is neither new in idea nor a new combination.

After some discussion of the case, the motion for injunction was ordered to stand to the hearing of the cause, the defendant undertaking to keep an account.

Mr. Fry, Q.C., and Mr. Solomon appeared for the plaintiff; Mr. Eddis and Mr. Everitt for the defendant.

COURT OF EXCHEQUER, WESTMINSTER.
NOVEMBER 19.
(Sittings in Banco, before the LORD CHIEF BARON, Mr. Baron CHANNELL, Mr. Baron PIGOTT, and Mr. Baron CLEASBY.)
SAXBY AND ANOTHER v. MACKENZIE AND OTHERS.

THIS was an action brought by the plaintiffs for an alleged infringement of their patent, dated June 24, 1856, for improvements in railway signal apparatus. The action was tried before the Lord Chief Baron in June last, when a verdict was entered for the plaintiffs on all the issues.

Mr. Grove, Q.C., Mr. Keane, Q.C., Mr. Macrory, and Mr. Aston appeared for the plaintiffs; the Solicitor-General, Mr. Webster, Q.C., and Mr. O'Hara Moore appeared for the defendants.

A rule for a new trial to enter the verdict for the defendants was moved for and obtained by the Solicitor-General, and came on to be argued some days ago, and the arguments have been resumed from time to time.

The defendants contend that they do not infringe the plaintiffs' patent, because they do not lower their signals by the action of the same lever that moves the shunting points, and simultaneous with that motion use another lever for that purpose. For the plaintiffs it was urged that the plaintiffs' invention consisted of apparatus by means of which the lever that works a shunting point, in order to open or shut a line of rails, also works the signals, and that in such a way that certain stops are interposed to prevent contradictory signals from being given, and the requisite stop is released to allow the proper indicating signal to be given. The plaintiffs' invention, it was said, was a system that for the first time, in 1856, provided the means of working railway signals with perfect safety. This was effected by causing the lever that moves points at the same time to stop or lock up in a position indicating danger all signals which, if lowered, would cause any collision or accident by permitting a train to go upon a line obstructed in any way by any point or other obstacle.

The defendants used, it appeared, the same mechanical means for moving a point and stopping contradictory signals, and releasing the proper indicating signal, but they also used an additional lever to move the indicating signal, instead of allowing it to fall by the action of gravity, and contended, on that account, that their apparatus differed from that of the plaintiffs.

The arguments in this case were concluded on Wednesday last, and their lordships have reserved their judgment.

ROLLS' COURT, CHANCERY LANE.
NOVEMBER 23.
(Before the MASTER of the ROLLS.)
CANNINGTON v. NUTTALL.

THIS is a patent case and involves the question hether the defendant has invaded the plaintiff's isting patent rights in respect of certain improvements in glass furnaces, whereby the glass is melted n bulk, and pots are dispensed with. The case is being tried by jury, and seems likely to occupy some days.

Mr. Grove, Q.C., Mr. Fooks, Q.C., Mr. Theodore Aston, and Mr. Carpmael appear for the plaintiff Mr. Webster, Q.C., Mr. Jessel, Q.C., Mr. E. Macnaghten, and Mr. Herschell for the defendant.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

ERRATUM.—In the list of specifications printed in our last issue, No. 1392, Messrs. Wilkin and Clark's for radiating axles, was marked "patent abandoned." This is not the case, the error having crept in by reason of the patentees having obtained an extension of time for completing their patent, which they have now done.

RECEIVED.—M. W.—B. L.—W. R.—T. C. S.—J. B.—S. and P.—J. F.—J. P.—W. M'L.—J. H. D.—R. S.—J. L.—R. T. C.—E. M.—R. A.—L. P. S.—R. W.—R. S. G.—C. H.—W. J.—W. F.—H. D.—S. W. B.—W. H. H.—R. E.—G. W. H.—J. S.—R. T.—A. W. P.—H. G.—W. and C.—F. B. and Co.—G. R. T.—F. H.—E. L.—H. M.

Meetings for the Week.

TUES.—Institution of Civil Engineers.—Renewed Discussion upon Mr. Gaudard's paper on "The Strength and Resistance of Materials," and also on "The Public Works in the Province of Canterbury, New Zealand," by Mr. Edward Dobson, A.I.C.E., at 8 p.m.

THE well-known painter of German historical subjects, Overback, lately died at Rome, aged 80 years.

Naval, Military, and Gunnery Items.

The Pacific Steam Navigation Company have contracted for the building of two new steamers for their Liverpool and Valparaiso mail line.

By direction of the Admiralty the ship in the grounds of the Marine School at Greenwich Hospital, and used hitherto as a training-ship for the pupils, is to be sold by auction.

The Viceroy of Egypt has ordered from a leading French mechanical company an iron floating dock. The dock will be of large dimensions, and will weigh 4,600 tons.

We regret to announce that a destructive fire took place yesterday week in the shipbuilding yard of Messrs. Oswald and Co., Sunderland, which resulted in a loss of extensive machinery and property, valued at from £20,000 to £30,000. No lives were lost.

The experiments which were to have been made at the Proof Butt, Royal Arsenal, Woolwich, to test one of a number of the 7-inch Moncrieff gun-carriages, invented to fire over high parapets—now under course of construction in the Carriage Department—have been postponed *sine die*.

The Board of Trade have awarded a binocular glass to Captain Th. Olsen, of the Norwegian ship "Vikingen," of Langesund, in acknowledgment of his humanity and kindness to the master and crew, 19 in all, of the ship "Athleta," of Newcastle, whom he rescued at sea on October 9, 1869, when in lat. 43 49 N, and long. 29 52 W.

The First Lord of the Admiralty has requested Mr. Tite, M.P., architect of the City of London Corporation, to supervise the division of Woolwich Dockyard into plots, preparatory to its immediate sale. It is understood that this is a compliment to Mr. Tite's well-known abilities as an architect, and that his services will be entirely honorary.

The opening of the Suez Canal goes on with the greatest festivity, fetes and feasts being the order of the day. Ships of all nations have passed through, some sticking in the mud on the way, and others, those of light draught, passing freely through. It would seem that there is still money required to complete M. Lesseps' great work, but this will doubtless be forthcoming as nations realise the importance and practical value of the undertaking.

A large quantity of Aberdare steam coal continues to be received at Pembroke Dock for the use of the navy, and it is rumoured that early next year the Channel fleet will again be sent to Milford to coal. This is the result of the trial made a short time since, when the vessels of the fleet were coaled at Milford with the most satisfactory results, both as to the price of the fuel and the quality of the coal supplied.

Her Majesty has sanctioned the employment of British officers in Persia to aid in the organisation and drill of the Persian army. There will probably be four officers thus employed—one with the local rank of brigadier, as commander, and three with the rank of colonel. One of the latter will belong to each branch of the service. It is rumoured that Major Moore, of the Bombay Staff Corps, and Major Peyton, of the 7th Dragoon Guards, may be employed on this service.

The number of ships arrived at Falmouth, Queenstown, Plymouth, &c., from Saturday, November 13, to Friday, November 19, both included, amounted, according to "Dornbusch's Floating Cargoes Morning List," to a total of 243:—66 wheat, estimated 172,600 quarters; 51 maize, estimated 153,000 quarters; 14 barley, 5 rye, 1 beans, 2 dodderseed, 4 linseed, 4 rapeseed, 1 oilcake, 2 valonea, 1 palm nuts, 6 rice, 10 sugar, 7 coffee, 1 tobacco, 4 hides, 8 guano, 2 nitrate of soda, 7 boneash, 6 dyewood, 14 timber, 1 fustic, 2 sulphur, 1 oil, 6 fruit, 17 sundries.

The trustees of the Tyne Lifeboat Fund met at their offices in South Shields on yesterday week, when the Mayor of that borough, on their behalf, presented to Mr. Joseph Smith, a veteran Tyne pilot, and superintendent of the Tyne lifeboat 25 years, an illuminated address, and a purse containing £30 in gold, as a mark of their estimation of his valuable services as superintendent of the lifeboats within the time mentioned. While occupying that responsible position Mr. Smith had gone off to 207 wrecked vessels, and had assisted in rescuing 1,001 lives.

It appears from a Parliamentary return that the total amount of the Banda and Kirwee prize fund, after deducting law expenses (upwards of £58,000) and agency commission at 1½ per cent. (£9,374 odd), amounted in round numbers to £615,600. Of this one-twentieth (£30,780) was paid to the representatives of Lord Clyde and Sir George Whitlock in the proportion of four-fifths (£24,624) to the former and one-fifth (£6,156) to the latter, leaving for general distribution £584,800. Three distributions have been made, amounting in all to 750 rupees (£75) a share.

The Henry-Martini 0·45-inch bore breech-loading rifles, about to be placed in the hands of troops for trial, are in an advanced stage of completion. The ammunition for these experimental arms has been decided on, and is now in course of manufacture at Woolwich. It is the Boxer small-bore breech-loading ammunition, similar in form to that for the service Enfield Snider arms, but having a solid hardened bullet and a powder charge of 85 grains.

Miscellanea.

The "Borsen-Zeitung" states that Messrs. Grattoni and Brassey and Dr. Strousberg have jointly undertaken to tunnel the St Gothard, and have engaged to complete the gigantic undertaking in less than seven years.

The Southmolton (Devon) Local Board have contracted to dispose of the town sewage, hitherto discharged into a stream, for five years for a sum sufficient to pay the interest on the outlay for sewage works.

The Turkish Government have granted a concession for the construction of the Roumelian Railways, and it is intended to issue 75,000 obligations of 400f. each, entitling the holders to certain lottery prizes.

The permanent buildings for the first of the series of Annual International Exhibitions of Art and Industry in 1871 were commenced on the 15th instant at South Kensington. Messrs. Lucas Brothers are the contractors.

The honour of knighthood conferred upon Mr. William Fothergill Cooke, which was recently announced, was recommended to Her Majesty as a recognition of Sir William's "special services in connection with the practical introduction of the electric telegraph."

It appears that in the fiscal year ending June 30, 1869, 760,000,000 letters passed through the mails of the United States, being an increase of 40,000,000 over any previous year. This is about 20 letters per head for every man, woman, and child in the United States.

The Council of the Society of Arts have appointed a committee to consider and discuss questions, relating to mechanical inventions, which may appear to be of too technical a character to be brought before the Society at the Wednesday evening meetings.

The seventh yearly issue of the Railway, Banking, Mining, Insurance, and Commercial Almanack, and annual review of the material interests of the United Kingdom, will be published early in January, 1870. It will be edited, as usual, by Mr. W. Page Smith, whose name is a guarantee that it will be found as useful as its predecessors.

Numerous accounts from Scotland and the North of Ireland state that on Monday week, between seven and eight o'clock p.m., a magnificent auroro aorealis was observed stretching over the entire heaven from S.W. to N.E., in shape like an enormous rainbow. It was very broad and luminous, and presented a remarkable appearance.

The improvements in Florence are going on apace The squares are beginning to be planted. The great bare Piazza dell'Indipendenza has had a trench dug round it and filled with good black mould, in which trees are to be set. The Piazza San Spirito is being converted into a pretty garden, with trees, shrubberies, and flowers, and something of the same kind is doing at St. Marco's-square.

Germany has had its public competition for the best drama on the occasion of the Shakspeare jubilee. A triennial prize of £3,000 and a large gold medal are given away. The successful competitor at present is M. Emmanuel Giebel, his work being entitled "Sophonisba." The second prize was gained by the author of "The Countess," M. Henri Kruse, editor of the "Cologne Gazette."

The "Wall-street Journal" says that Mr. Drake, who put down the first petroleum oil well in America, and who at one time was worth £200,000, recently died in the poor-house. The first derrick and engine still stand over the well, and are carefully preserved. A monument is to be erected to his memory, which will contain a room in which the engine is to be placed.

Dr. Lacaze, who has left his fine collection of pictures to the Louvre, has bequeathed twelve thousand pounds to the Academy of Sciences of Paris, to found three biennial prizes, of £400 each, for the most important works on physiology, natural philosophy, and chemistry. The conditions of the bequest are that the prizes shall not be divisible, and that they shall be open to competition by foreigners as well as Frenchmen. Should they be won by scientific men of other nations, says the testator, the honour will still remain to France, that the prizes resulted from a French donation, and were awarded by a French Academy.

The Post-office department of the United States' Government, keeps a register of the time occupied in the transmission of the mails between San Francisco and the chief eastern cities. The average time between New York and San Francisco is 7 days 2 hours 23 minutes; but frequent trips have been made in less than 6 days and 16 hours. It is intended to reduce the schedule time, so as to bring it down by half a day on the average.

The Southern Embankment of the Thames, which reaches from Westminster Bridge almost up to that of Vauxhall, being now completed, it was opened on Wednesday by Sir John Thwaites, with some slight ceremonial. A procession was formed to the southern extremity, headed by a band, salvos of artillery were fired, and the church bells of St. Mary, Lambeth, rang out a succession of merry peals.

Experiments have recently been made at Usworth Pit, near Newcastle, with Mr. S. P. Bidder's coal-cutting machine. The result was eminently satisfactory. Twenty-five tons of coal were set free in the remarkably short space of 35 minutes. Unlike the ordinary hewing, the coal was left in very large pieces, and by the prevention of waste in this way alone the saving in certain collieries to coalowners must be immense.

In the old churchyard of Worth, Dorsetshire, is a tomb with the following inscription:—"Benjamin Jesty, of Downshay, died April 16, 1816, aged 79. He was born at Yetminster in this county, and was an upright, honest man, particularly noted for having been the first person known that introduced the cow-pox by inoculation, and who, for his great strength of mind, made the experiment from the cow on his wife and two sons in the year 1774." This man was therefore the first vaccinator.

The number of visitors to the South Kensington Museum during the week ending November 20, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,671; Meyrick and other galleries, 1,268; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,592; Meyrick and other galleries, 76; total, 14,607. Average of corresponding week in former years, 9,612. Total from opening of Museum, 8,959,371.

W. Turgan has just issued some new numbers of his valuable work, "Les Grandes Usines." They contain a most interesting description of the manufacture of Venetian glass and that of the factitious pearls which are used as a substitute for money in dealings with savage and uncivilised nations. The subject of the working of mines of silver, lead, iron, and coal, is also treated *in extenso*, and the various portions of the text illustrated by several very handsomely executed plates. At some future occasion we shall lay before our readers a *resume* of the contents we have alluded to.

According to official returns, the number of chamois killed this year in the mountains of Glaris is as follows:—25 in the Grossthal, 32 in the Sernithal, 10 in Mittelland, and 12 in the Kerentz country; making altogether 79. These figures show that the number of hunters goes on increasing, and that the slaughter of these animals becomes more and more numerous in a corresponding ratio. Thus this interesting race of inhabitants of the Upper Alps is fast approaching extinction, especially in all those districts where the shooting is free. The only remedy appears to be the enactment of some law to prevent it.

With the view of bringing Australian meats, and the various modes of cooking them, prominently before the working classes, several of the leading colonists have determined upon providing a banquet, which shall be prepared entirely by the wives of *bona fide* working men, and which will take place at Lambeth Baths on Wednesday, December 1. The Earl of Denbigh, if in town, will preside, and the list of stewards includes the names of many of the leading noblemen and Members of Parliament who take an interest in improving the social condition of the working classes. The guests are to be selected by the Working Men's Club and Institute Union, and it is intended that the working classes of London shall be fairly represented. Each of the invitations will be for a husband and wife.

The Austrian Government has introduced a novelty in postage, which might be introduced with great benefit in all countries. The object is to enable persons to send off, with the least possible trouble, messages of small importance, without the trouble of obtaining paper, pens, and envelopes. Cards of a fixed size are sold at all the post-offices for two kreutzers, one side being for the address and the other for the note, which may be written either with ink or with any kind of pencil. It is thrown into the box, and delivered without envelopes. A halfpenny post of this kind would certainly be very convenient, especially in large towns, and a man of business, carrying a few such cards in his pocket-book, would find them very useful. There is an additional advantage attaching to the card, namely, that of having the address and post-mark inseparably fixed to the note.

THE ninth decennial census of the United States will be taken in 1870. With a population sparsely scattered over a vast area, no attempt has hitherto been made to complete the enumeration in one day; in some cases it was allowed to spread over the whole year. It is thought that by proper arrangement the whole work of enumeration and reporting the schedules may be performed within a month. The cost of the census of 1860 exceeded 1,535,000 dols. It is doubted whether too much has not been attempted, and whether some of the subjects of inquiry might not be omitted. Some portions of the returns have been found of little or no scientific or practical value.

ANOTHER revolution in farm practice is about to be worked out. Mr. James Howard, M.P., has turned his attention to the question of drilling by steam power, and has had a drill, upon the Suffolk principle, constructed with a harrow in the rear. During last week the machine was regularly at work upon the farms of Messrs. Howard, Bedford, and upwards of 20 acres per day were drilled and harrowed; 16ft. is covered at a bout. On Friday week 15 acres of wheat were put in before dinner, when a heavy rain stopped the work. A self-propelling engine is employed to haul the drill. The apparatus is moved from field to field without the aid of horses, and is ready for work within the short space of an hour. By a very simple device the slack rope, working on a pulley at either side, turns round the drill and harrows when the end of the field is reached.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1361, 1362

BUILDINGS AND BUILDING MATERIALS—1338, 1339, 1357, 1366, 1399

CHEMISTRY AND PHOTOGRAPHY—None

CULTIVATION OF THE SOIL, including agricultural implements and machines—1338, 1336, 1365, 1369, 1380, 1383, 1387

ELECTRICAL APPARATUS—None

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1337, 1343, 1346, 1358, 1369, 1392, 1394

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1349, 1370, 1381, 1393

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1355, 1359, 1364, 1368, 1386, 1400

GENERAL MACHINERY—1333, 1375

LIGHTING, HEATING, AND VENTILATING—None

METALS, including apparatus for their manufacture—1350, 1372, 1391

MISCELLANEOUS—1332, 1334, 1341, 1344, 1348, 1352, 1365 1371, 1378, 1388, 1390, 1398

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1340, 1345, 1347, 1356, 1373, 1376, 1382, 1395, 1396, 1397

SHIPS AND BOATS, including their fittings—1351, 1384,

STEAM ENGINES—1331, 1354, 1374, 1377, 1385, 1389

WARFARE—1342, 1379

1331 F. JACKSON and T. CORBETT, Wigan. *Lubricators to steam engines.* Dated April 30, 1869.

The inventors employ a receiver or vessel fitted with a plug having a cup at the top, and bored partly down the centre to conduct the oil into the receiver or vessel, and partly upwards from the bottom to admit the steam and also to remove the condensed water. The holes in this plug and also in the conical tube (inside the receiver) in which it works are so arranged that in one position of the handle the passage communicating from the cup with the inside of the receiver or vessel is open and the other passages are closed. In this position the vessel is charged with oil or tallow.—Patent abandoned.

1332 F. BUJEAUD, Angouleme, France. *Bottle envelopes.* Dated April 30, 1869.

The straw, cane, rush, or other analogous material of which the bottle envelopes are to be made is arranged on carriages, and then sewn by means of the improved sewing machine, having two needles and two shuttles. When the sewing is effected, the inventor removes the sewed straw from the carriage and forms it into a cylinder by tying the free ends of the sewing threads, and then by tying in one of the ends about an inch from the extremity he obtains a conical envelope which serves to cover the bottle.—Patent completed.

1333 A. SLEIGH, Lancaster-road, Notting-hill. *Motive power.* Dated April 30, 1869.

The inventor fixes vertically two discs or wheels with spokes of the same diameter and size on one common horizontal axle at any desired distance apart, and unites those discs or wheels by transverse bars, so as to make them one wheel, which he calls the main wheel, the axle of which rests on and revolves in bearings supported by a perpendicular frame work. The periphery of the main wheel is divided into several equal segments; eight are adapted at present; externally to each of those segments, round the main wheel, oblong square blocks are adapted, which are termed segmental blocks, of any heavy substance.—Patent abandoned.

1334 R. F. BIGOT, Paris. *A level with mirror.* Dated April 30, 1869.

This consists of a looking glass with a plane surface. This glass is placed in a frame and is suspended in any suitable manner upon an elbow rod bent at a right angle, which is in its turn fixed to a cursor or slide sliding along the rod which carries the instrument. Two screws fix the elbow rod to the cursor. This rod may be moved up and down at will, so that the fiducial line or line of sight may be always at the height of the zero on the vernier or graduated scale.—Patent abandoned.

1335 J. R. JEFFERIES, Ipswich. *Horse rakes.* Dated April 30, 1869.

The inventor employs a frame of flat bar iron, which he furnishes with shafts and mounts on carrying wheels. These wheels turn on stud axes carried on cranked levers pivoting on the frame, to afford means of adjusting when desired the height of the frame, and therefore the position of the points of the rake teeth, in relation to the surface of the land. The front bar of the frame has two or more cylindrical bosses fixed upon it, a lever arm projecting forward is mounted on each of these bosses, and these arms carry a bar on which the rake teeth are supported and on which they are able to turn. Each of the lever arms above mentioned has another lever arm formed in one piece with it and projecting to the rear. These arms carry a bar passing along under the rake teeth and supporting them.—Patent completed.

1336 H. J. SEELS, Lincoln. *Harrows.* Dated April 30, 1869.

The inventor forms the harrow frame approximately of a triangular form, and at the leading angle he provides a swivel wheel, on the upright spindle of which is fixed an arm or long eye to which the draft chain of the implement is connected so that the position of the swivel wheel follows the direction of the draft. Near the back of the frame a horizontal axis is mounted upon it having at its ends arms on which other supporting wheels are carried on studs. There is also a lever handle fixed on the axis at its centre, by depressing or raising which the inclination of the arms carrying the wheels is varied; when these arms are vertical or nearly so, then the wheels are depressed so far below the frame as to carry the points of the teeth clear of the surface of the land, but when the arms are, by raising the lever handle, brought to a horizontal or nearly horizontal position, then the harrow teeth penetrate the land to the full depth of which the implement is capable, and the harrow when drawn along the ground acts in the manner of an ordinary harrow.—Patent completed.

1337 R. CRAIG, Dalkeith. *Manufacture of paper.* Dated April 30, 1869.

This invention consists in certain improvements in the machinery of the Fourdrinier paper-making machine. As such machine and cylinder are used at present, there is only one press roll which is usually in a position immediately under the cylinder. The inventor, however, in addition to the single press roll now used, places at least one additional press roll situated at a distance of about 1ft. in front of the first-mentioned press roll.—Patent completed.

1338 R. WARD, Newcastle-on-Tyne. *Ovens.* Dated April 30, 1869.

The inventor constructs a furnace underneath the apparatus, the heat from which operates upon the under side of a bed plate, first by immediate action and next by means of a flue which passes round it. Upon the bed plate in the centre he erects a tube in a vertical direction, into which the heat is conveyed after having traversed the under side of the bed plate. Round this table he places any desirable number of movable shelves for receiving the articles to be subjected to heat, these shelves being constructed with a hole in the centre to receive the vertical tube. Each shelf may thus be caused to revolve round the tube for the purpose of conveniently receiving or removing the articles to be treated.—Patent completed.

1339 E. TUTTE, Fareham. *Hollow walls.* Dated April 30, 1869.

In order to tie the double wall together the inventor employs wall ties consisting of thin plates usually of slate or cast iron, and generally of a width slightly exceeding the thickness of a brick, and of a length sufficient to extend across the air space in the wall and to enter the brickwork on either side. The wall ties may be perforated at either end, so that a mortar may hold to them firmly. As the wall is being built they are introduced at distances apart into the vertical joints, and their width being by preference as before mentioned somewhat more than the thickness of a brick, the lower edge of each wall tie then rests on the course below it, whilst the course above it bears upon its upper edge. Thus the wall ties become fixed very securely in this brickwork, and great strength is given to the structure.—Patent completed.

1340 J. SMITH, Rathgar, Dublin. *Communicating in trains.* Dated April 30, 1869.

This consists in having a water pipe or pipes attached to each carriage with a convenient means of uniting them by means of a hose and union joint, so as to make a watertight or nearly watertight coupling. When such pipes are so joined, a free communication will be effected along the whole length of the train.—Patent abandoned.

1341 T. GREENWOOD, Leeds. *Cutting joints.* Dated May 1, 1869.

The inventor constructs a framing or bed having slides formed along each side, upon which slides is a table holding the two pieces of wood to be acted upon. This table has two opposite inclined surfaces placed at any desired angle to each other, depending upon the angle at which the two boards require to be joined together, such angle formed by the inclined surfaces being if requisite rendered adjustable. Upon these inclined surfaces are placed the boards on which the dovetail joint is to be cut, which boards have previously had a true edge formed to be acted upon by the cutters. The exact required length of the boards is determined by causing such edges of the board in passing down the inclined surfaces to come against adjustable gauge blocks with inclined surfaces situated upon a transverse bar carried by the bed of the machine. When in this position the boards are held securely against the angular surfaces of the table by two lever cramps made to act by means of a screw upon a saddle piece resting on the board, or any other convenient known mode of cramping may be employed. The table is caused to travel along the bed of the machine by means of two screws mounted in the framing or bed, and rotated simultaneously by means of a hand wheel and suitable gearing or by a self-acting feed motion.—Patent completed.

1342 J. MACKIE, St. James-street, S.W. *Breech-loaders.* Dated May 1, 1869.

This relates to letters patent dated May 7, 1860 (No. 1128). The inventor forms what is called the action of the gun so that when the breech is closed and the gun ready for firing, the breech end of the barrels being close up to the false breech and firmly held there by the eccentric head of the lever, the hook which corresponds with the hook of Dougall's lock-fast gun, and which is at the front end of the lump instead of resting against the hinge pin as in the lockfast, is at a little distance behind it. The cavity in the lump in which the head of the lever works closes down upon a solid piece left in the action of the gun, and so arranged that the solid piece and the eccentric head of the lever together exactly fit and fill the cavity.—Patent abandoned.

1343 J. WILSON, Stockport. *Bobbins.* Dated May 1, 1869.

This relates to the tubular bobbins without ends used in all such machines where "presser flyers" are employed, and consists principally in forming such bobbins from a piece of sheet iron cut to a suitable width, and bent by means of rollers or dies into a cylindrical or tubular form. —Patent completed.

1344 W. B. ROBINS, South Molton-street. *Syringes.* Dated May 1, 1869.

The inventor constructs a pump or syringe capable of delivering a constant stream in the following manner:— The apparatus consists of a barrel in which a piston works. This piston has a tubular rod through which the delivery takes place, and it terminates in a jet or rose at which the water escapes. The rod works through a stuffing box at the end of the barrel and has a handle upon it which is grasped by the hand in working it to and fro. The inlet or suction pipe is connected with the barrel at or near the stuffing-box end and the water is drawn into the barrel during the inward stroke. When the outward stroke commences this water, being prevented from returning by the suction valve, is allowed to pass from the front to the back of the piston by passages in the piston rod, over which the piston, which is loose on the rod, plays, acting like a valve. During the inward stroke the piston stands over these passages closing them, but as soon as the outward stroke of the piston rod commences the stop on the rod which had been propelling the piston leaves it, and the rod slides through the piston until another stop comes against it and causes it to commence its return. This motion of the piston rod independently of the piston, opens the passages in the rod and then the water passes by these passages to the back of the piston.—Patent completed.

1345 E. and T. WALTHAM, Stockwell. *Road locomotives.* Dated May 1, 1869.

The frame or body of the engine is adapted to carry upon it the load which is to be transported and also a steam boiler, by preference an upright boiler such as is known as "Field's Boiler." This frame or body is supported by two locking or swivelling frames, one at the front the other behind, and each of these frames has two supporting wheels, which are the road wheels of the engine. Each locking frame turns upon a perch pin, and the frame or body is supported by friction rollers running on a circular track on the locking frames. The locking of the leading frame is effected by any suitable arrangement of steering gear, and the two frames are geared together by toothed arcs so that they turn simultaneously. Either locking frame carries upon it two steam cylinders driving by means of connecting rods an axis having corresponding cranks, and from this axis motion is transmitted to the road wheels by gearing suitably arranged to allow free play to the springs interposed between the frame or body and the axles. There are two tooth rings on each road wheel, one with external the other with internal teeth, the driving pinion is between them and is able to be put into gear either with one or with the other by moving a block carrying the pinion axis in a suitable guide slot.—Patent completed.

1346 J. P. BALM, Halifax, and R. NEWTON, Keighley. *Spinning frames.* Dated May 1, 1869.

This consists in giving a transverse motion or a reciprocatory endwise movement of the bottom front carrying roller, thus producing a frictional sliding of the same against the top roller. Also in covering one or both of the front carrying rollers with either india-rubber, leather, or other suitable substance to produce adhesion on the rovings as they pass through or between them to the drawing rollers.—Patent completed.

1347 J. B. BLAKE, Alton, Hants. *Velocipedes.* Dated May 1, 1869.

This relates to velocipedes with three wheels, namely, two running wheels and one steering wheel. The running wheels are fixed on an axis fitted with cranks in the usual way, but the axle of the steering wheel is formed with a spherical swell about the centre of its length, and in this spherical part the nave of the steering wheel fits, thus enabling the wheel to be moved sideways without changing the position of the axle. The wheel may be maintained in a vertical position by making the steering spindle forked so as to embrace each side of the nave of the wheel and allow freedom of movement sideways on the axle. The steering wheel is connected to its axle by a pin fitting in a slot.—Patent abandoned.

1348 G. RITCHIE, Folkestone. *Stop hinges.* Dated May 1, 1869.

The inventor constructs a hinge for this purpose of a plate of metal adapted to be fixed to one of the pieces or parts to be connected by screws or other fastenings and having a boss upon it through which the pin of the hinge is passed. On either side of the boss a metal plate is applied; these plates are adapted to be fixed to the other of the two bars, pieces, or parts, to be connected, one on either side of its extremity, by screws or other fasten-

ing. The hinge pin passes through the ends of the side plates at the corners of the plates, and the plates are secured by riveting the ends of the hinge pin.—Patent completed.

1349 W. BROUGHTON, South-street, Finsbury, and T. STEVEN, Glasgow. *Cooking range.* Dated May 1, 1869.

This relates, first, to arrangements for holding or placing the screw nut used in uniting the parts of cooking ranges and other fireplaces; second, to constructing, arranging, or combining together the parts of cooking ranges; third, to constructing and arranging the hood or "back draught" in an improved manner; fourth, to employing a double shovel for supplying fuel into the middle of a fire; fifth, to casting of the oven with the shell forming the outside of the flue in the same piece; sixth, to arranging a cooking spit horizontally in the oven and the application of the turning power thereto; seventh, to turning cooking spits, ventilators, and other appliances by motive power apparatus.—Patent completed.

1350 J. CONWAY, Broad-street, Ratcliff. *Forges.* Dated May 1, 1869.

Instead of forming the tuyere pit or well-hole of the hearth of the forge with a close bottom in the usual way, the inventor forms it with an open bottom or makes an opening therein when the hearth has been already formed in the usual way, in which opening, as the case may be, he fits a cast-iron grate and frame of a rectangular or other shape, this grate being removable from the frame at pleasure and reversible therein so that when one end thereof has been burnt away the opposite end can be turned to the tuyere.—Patent completed.

1351 R. SAUNDERS, Croydon, S. *Cable stoppers.* Dated May 1, 1869.

The cable stopper or controller is constructed, arranged, and combined with the elastic devices in such a manner that the entire apparatus occupies but little more space than an ordinary stopper, and may be taken away and stowed below with the anchors when the latter are no longer required. In carrying out the invention the stopper proper or controller may be of any suitable construction, but, instead of being rigidly secured to the decks as is now generally the case, it is to be placed on a metal plate, in which may be made grooves or other guides for the stopper to work upon.—Patent completed.

1352 C. T. LIERNUR, Frankfort-on-the-Maine. *Treating sewage.* Dated May 3, 1869.

This consists in various improvements in the details of M. Liernur's previously patented pneumatic sewerage system, the principal advantage of which over other systems is, according to the inventor, that while by the latter only one portion of the excrements is utilised, the other being left to cause annoyance, by his system the whole of the excrement is deodorised and usefully employed.—Patent completed.

1353 P. BARRY, Lombard-street. *Printing machine.* Dated May 3, 1869.

The inventor prefers to arrange in connection with the feed apparatus and over the table whereon the sheets are piled a bar or roller, the surface of which is partly or entirely covered with porous india-rubber, preferably of the kind now known as sponge rubber, but he may employ other similarly soft, porous, and durable material, which, when brought in contact with the paper, will separate the upper sheet from the others without soiling or otherwise injuring the paper. The inventor attaches this rubber in any suitable manner to the bar or roller before mentioned, which is arranged at the end of the sheet to be presented to the grippers, and which may extend entirely across the same. Where a bar is used it is necessary that the same should be provided with means whereby it will adapt itself to the varying thickness or height of the pile or layer of sheets on the table, and the bar must also have at proper intervals a motion which will separate the upper sheet from the other sheets below it, and present its edge to the grippers or tapes which then seize it and carry it forward to the printing bed or rollers.—Patent completed.

1354 J. SHACKLETON, Bradford. *Utilising waste steam.* Dated May 3, 1869.

The inventor employs a self-acting regulator valve to the ordinary exhaust pipe of the steam engine, and also any suitable arrangement of piping connected to the exhaust pipe between the valve and the steam engine, for conducting the exhaust steam to the place and for the purposes required. This valve is constructed similar to an ordinary mushroom stop valve, but the valve is under the action of a spiral spring, which is regulated or adjusted by a set screw to any desirable amount of pressure, so that the exhaust steam will open the valve and escape by the ordinary exhaust pipe.—Patent completed.

1355 S. H. HODGES, Bristol. *Boot heels.* Dated May 3, 1869.

A column, having a shoulder or flange at the upper end thereof, is fixed by means of suitable supports in a vertical position, the same being hollow and having in the interior thereof a spiral or other spring. A solid piston or plunger is placed in the hollow portion of the column, in which it is free to have an upward and downward motion above the spring, and is kept in its desired position by means of suitable projections and grooves formed on and in the piston or plunger and column respectively, or by means of any other suitable or analogous contrivance. A block is fixed to the head or upper part of the piston or plunger, such block being perforated with circular or suitable holes corresponding in number to that of the nails which it is intended shall be inserted in the heels to be manufactured. In each of the holes is placed a metallic pin, the length of such pins being equal to the thickness of the block. A block, in which is formed the heel die,i s attached by means of a suitable hinge to the piston block, so that it can be lifted and turned over on one side, leaving the upper face of the latter exposed.—Patent completed.

1356 H. WILLIAMS, Portwood-street, Liverpool. *Velocipedes.* Dated May 3, 1869.

The invention chiefly consists in having the fore or driving wheel of great diameter. This fore or driving wheel is supported from the axis by a wrought-iron or steel forked eye rod, which is fitted into the bearing socket in the beam or frame. This wheel is driven by double cranks on each side of the wheel worked by the rider by means of treadles or levers working on pins secured to brackets attached to the forked eye rod before mentioned. These treadles are nicely balanced by means of counter weights placed on the opposite end of the treadles to that from which the impetus is given in order to reduce the pressure or weight against the back stroke of the cranks. The balanced ends of these treadles are brought to bear on the under side of the cranks and impel them.—Patent abandoned.

1357 J. B. NIMMO, Edinburgh. *Lever door spring.* Dated May 3, 1869.

The apparatus or contrivance employed consists of two levers acting in gear with a bevelled or other wheel or pinion, and both resting on centre bearings. They operate by means of a compensation balance weight or weights suspended from the two levers. The top of the spindle of the pinion is squared, and on this is fitted an iron strap which supports the door or gate, and which is attached in the usual way. The spindle and pinion or wheel are best made in one piece, but may also be made separately and keyed together. The whole is fitted into a cast-iron case or frame, which is fitted into and flush with the floor. —Patent completed.

1358 B. HUNT, Serle-street, Lincoln's Inn. *Spinning hemp.* (A communication.) Dated May 3, 1869.

The material turns as well as the flyer, but the barrel on which it is wound does not turn, that is to say, that the sliver turns in the same direction and at the same speed as the flyer, and the thread passing from the latter is wound on a barrel turning on its own axis so as merely to take up the thread as it is spun, but completely independent of the rotary movement of the flyer which effects the twisting.—Patent completed.

1359 D. P. WRIGHT and C. BUTLER, Birmingham. *Paraffin lamps.* Dated May 3, 1869.

This consists in using a thin sheet metal base formed into a bell mouth or spreading shape, by preference serrated, perforated, or vandyked on its lower edge for air way, and into this the inventors fit a perforated convexed disc, to which disc a concentric tube is secured or formed for receiving the rectangular cotton holder and regulator, the lower end of the tube before mentioned being screwed or otherwise in the ordinary way for screwing into the oil vessel. The spreading or bell mouth base contracts and terminates upwards with a perforated concentric disc formed of the same or applied within the top edge or flange and shoulder below, which is by preference a row of perforations, and around the flange is placed a bezel or gallery for supporting a glass shade having a concentric row of perforations.—Patent completed.

1360 F. W. KASELOWSKY, Bielefield, Prussia. *Separating fibre.* Dated May 3, 1869.

This relates to letters patent dated October 4, 1866 (No. 2,564), the object being to break up and more effectually separate than heretofore the "boon" or woody part of flax and other like fibres from the "lint" or useful part of the fibres without breaking or wasting the useful fibres. This object is attained by the use of a novel arrangement of blades made of steel, iron, or other suitable substance, between which the fibres are passed in order that they may undergo a breaking and scraping operation.—Patent completed.

1361 P. SOUTHERN, Aspull, Wigan. *Furnaces.* Dated May 3, 1869.

The inventor employs circular firebars placed transversely of the furnace. These bars at their ends are supported in bearings on the side plates of a frame which is mounted on wheels so that it can be run in and out of the furnace, and this frame also carries the hopper containing the fuel. The circular firebars are corrugated with longitudinal and also with transverse corrugations passing around them, and have each a slow revolving motion imparted to them so that they shall carry forward the fuel from the hopper continuously into and through the furnace.—Patent abandoned.

1362 W. SEED, Preston. *Furnaces.* Dated May 4, 1869.

This consists in the use of a self-feeding rotating internal circular grate supported on rollers and turned slowly round by steam or other power. The fuel is supplied at one side to the interior of this internal circular grate, and is gradually consumed as the grate rotates, the clinkers being collected in a chamber within the internal circular grate; the products of combustion are conveyed from the furnace to the flues of a steam boiler, or to the flues of a heating apparatus, or to any other apparatus to which the furnace may be applied.—Patent completed.

1363 E. THOMAS, sen., and E. THOMAS, jun., Melford, and J. MORRIS, Welshpool, Montgomeryshire. *Agricultural implement for forming ridges.* Dated May 4, 1869.

This implement consists of a framework composed of two long bars placed parallelly or side by side, and maintained or held in that position by shorter or crossbars, staves, or bolts. The two parallel bars have handles or tails similar to those of a plough. The framework thus formed carries two iron plough bodies by means of two horizontal bars which project on each side of the framework. The plough bodies are formed with shares and shield boards, which incline inwards or towards each other in such manner that when in use they push the soil from the outside of the implement towards its centre, so as to form a complete ridge. The plough bodies are made to slide upon the horizontal bars, so that the width of the ridge may be varied as may be desired. A wheel mounted on an axle is provided at the fore part of the implement, and its axle is carried in two slides, in which slides it may be fixed at any desired height, by an arrangement of levers. In this way the height of the wheel may be adjusted in accordance with the size of the ridge.—Patent completed.

1364 C. TOPHAM, Coleman-street, Bunhill-row. *Mince knife.* Dated May 4, 1869.

This consists, first, in the construction and use of a peculiar knife box or box for securely holding the cutting or dividing blades in such manner that the upper plate of the box has a number of slots into which are passed the tangs of the knife blades. These tangs are so formed that, at their lower ends, they have at one side a projection which fits into a recess in one of the side plates of the box, such side plate being a fixed plate, so that, when the opposite or movable side plate is secured in its place by screws or other means of fastening the knives are fixed in such a manner as to be ready for use.—Patent completed.

1365 R. WAPPENSTEIN, Manchester. *Omnibus register.* Dated May 4, 1869.

The inventor employs for each journey or stage a meter having two sets of dials and fingers, one set for the inside of the omnibus, and the other set for the outside, and the dials are marked to indicate units, tens, and for calculating hundreds and thousands. The meter corresponds with a stationary dial having two series of numbers and two fingers turning on arbors independent of each other, and one of the series of numbers and one finger are used for the inside of the omnibus, and the other series and finger for the outside, and the numbers are 1 to 23 or other number higher than can be carried according to the size of the omnibus.—Patent completed.

1366 T. COCKCROFT, Hebden-bridge. *Window sashes.* Dated May 4, 1869.

This consists in coupling and suspending the two parts or sheets of a sash together by one cord and pulley at each side of the window, and thereby dispensing with sash weights, and consequently all preparations for their movements behind the frame, and the making of pockets for access thereto, also only requiring two pulleys and cords to each sash or window of two sheets instead of four as heretofore.—Patent completed.

1367 The time for filing this specification was extended by the Lord Chancellor. The abstract will probably appear in our next number.

1368 R. FENNELLY, Wellington Chambers, London-bridge, E.C. *Cases for meat.* Dated May 4, 1869.

The inventors employ a case of wood lined internally with felt or non-conducting material. Within this is placed a double case of sheet metal. The interior of this case is suitably fitted up to receive the meat to be conveyed from one place to another, and the space between the double sides of the metal case is to receive a cooling medium.—Patent abandoned.

1369 T. PERKINS, Hitchin. *Reaping machines.* Dated May 4, 1869.

The inventor employs for actuating the clutch by which the acting parts of the machine are thrown in and out of gear with the driving wheel a lever arm at the rear end of an axis, which, at its forward end, is provided with a lever handle within reach of a driver sitting on the seat upon the pole. The forward end of the axis is supported by a bearing on the pole, or it might be a shaft which carries the seat, whilst the rear end of the axis is supported by a bearing or bearings on the framing of the machine. Or a lever, supported in a bearing upon the pole or shaft, might otherwise be caused to work the engaging and disengaging clutch, as, for example, by employing a bell crank to give motion by a connecting rod to another bell crank that acts upon the clutch.—Patent completed.

1370 W. E. GEDGE, Wellington-street, W.C. *Raising and preserving beer.* (A communication.) Dated May 4, 1869.

This apparatus works under the pressure of carbonic acid gas, the pressure varying according to circumstances. It is composed, first, of a vase termed the acido, surmounted by a stopper for the introduction of the liquid; at the upper part of this vase is a tube which places it in communication with a generator, and an equilibrium of pressure is maintained by means of india-rubber tubing fitted at the lower part, and through which the acid flows into the generator. Second, of a vase termed the generator containing carbonate of lime. At the lower part of this vase is a cork termed the purging or blow-off cock. This generating vase is surmounted by a valve with flexible membrane, the movement of which permits a lever of a weight regulated for a given pressure to determine with precision the introduction of the acid by the tube coming from the acido vase into the generator by means of a throttle pressure exercised by the weighted lever on the tube coming from the acido vase in order to constantly maintain the proper pressure for working the apparatus.—Patent abandoned.

1371 A. and E. FAU, Castres, France. *Washing skins.* Dated May 4, 1869.

The inventors submit woolly skins, clogged with thistles, clot burs or goose grass, to a preliminary soaking in water. They then place one or several of the skins on a cylindrical drum preferably of a conical shape, and movable or rotary, or upon inclined planes, or any kind of surfaces, movable or fixed. And they direct on to these skins one or several jets of water under pressure obtained by means of a natural or an artificial fall, or of pumps worked by any available motive power.—Patent completed.

1372 J. TALL, Southwark, and A. WILLIAMS, Great George-street, Westminster. *Shaping metal.* Dated May 4, 1869.

This consists in straightening, flattening, bending, or curving metallic sheets, plates, bands, bars, or rods by first heating them, and then, while in this state, clamping or securely holding them by the ends in a machine or apparatus in which they are gradually allowed to cool. —Patent completed.

1373 A. V. NEWTON, Chancery-lane. *Railway carriage wheels.* (A communication.) Dated May 4, 1869.

This consists in constructing the body of the wheel of two main cast-iron sections, which, when united or brought together, form a body which is divided transversely to its axis, and in so fitting these two main sections on the axle and combining with them a wrought-iron or a steel or other suitable tyre as that the friction of the sections on the axle is or may be made to hold them in place, and, by a peculiar construction of the outer peripheries of the sections and inner peripheries of the tyre, and otherwise suitably forming the sections. The tyre is crowded or wedged on the sections, and a tightness of fit secured for it, without shrinkage of the tyre, by simply forcing the sections together or pressing up the one section against the other.—Patent completed.

1374 W. E. NEWTON, Chancery-lane. *Forcing engines* (A communication.) Dated May 4, 1869.

This relates to a new kind of engine, the principal element of which is a hollow screw or helix, having its axis placed in an inclined position and arranged to rotate in suitable bearings. When used as a motor the spiral passage of the screw or helix is to such extent supplied or filled with water or other liquid that the lower portion of each turn of the helix contains the water or other liquid to such a depth as to form in the upper portion thereof a chamber for steam or vapour. The steam or vapour in the chamber thus formed in the several turns of the screw or helix acts in such a manner both by its direct pressure and expansive force upon the spiral surfaces of the screw or helix as to produce its rotary motion about its axis, and as this rotation is produced the steam or vapour and the water or liquid pass upward through the spiral passage of the screw or helix, at the top of which the steam or vapour escapes to the atmosphere or to a condenser, while the water or liquid enters a central passage formed through

the screw or helix and descends to the bottom thereof.—Patent completed.

1375 A. C. F. FRANKLIN, Abingdon-street, S.W., and E. DUBOIS, Primrose-street, Bishopsgate. *Gas engines.* Dated May 4, 1869.

This consists in using the gas on one side only of the piston or at one end of the cylinder, the other end of the cylinder being left open so that the piston is driven in one direction by the force of the gas, and in the other direction by the atmospheric pressure consequent upon a partial vacuum produced by the sudden escape of the gas under pressure from the cylinder at the end of the spoke.—Patent abandoned.

1376 T. SIBLEY, Ashton-under-Lyne. *Velocipedes.* Dated May 5, 1869.

The inventor makes the front or driving wheel with its axle fixed at right angles to the length way of the frame, and makes the back wheel into the guide wheel by arranging it so that it can be turned as required. The forked parts for carrying the bearings of the wheels are cranked or bent outwards so that the frame may be shortened, and so that a tendency will be given to the guide wheel to keep in a straight line.—Patent abandoned.

1377 D. ADAMSON, Newton Moor, near Chester. *Steam engines.* Dated May 5, 1869.

This consists, first, in various improved cylindrical and segmental valves, both with and without cut-off valves. Second, in the improved portable and other steam boilers. And, last, in apparatus for blending flanges on portions of steam boilers.—Patent completed.

1378 J. F. KENT, Thornton Heath, S. *Mortising machine.* Dated May 5, 1869.

This consists in fixing the cutting instruments upon a rectangular frame working in vertical guides upon an upright stand, and actuated by a lever supported upon a fixed stud bearing secured to the said stand, in which the frame works with an up and down movement, in connection with which an horizontal bench or table is employed provided with a travelling bed or movement worked by a rack and pinion, hand wheel, and ratchet motion (in gear with the lever) for bringing the work forward to the cutters as may be required, so that upon the wood being placed upon the bench regulated by a gauge plate, and brought forward to be mortised or tenoned, the ordinary cutting instruments are caused to operate upon the work by the descent of the lever in connection therewith.—Patent abandoned.

1379 G. CLARK, Northumberland-street, W.C. *Cartridges.* Dated May 5, 1869.

This consists, first, in a method of adhesion of paper or cloth to sheet metal, forming what may be termed metallic paper or cloth, by the following means:—First, by covering the metal with a coating of varnish, which when dry, will harden and firmly adhere to the metal without cracking, such as gold size or any other combination of resinous materials producing the same results then to cover the paper or cloth with paste or gum mucilage, and apply the paper so covered, whilst in a wet state, to the varnished surface of the metal; second, in the construction of a strong case. The tube or case proper may be made of a coil of the above named metallic paper or cloth, or it may be a welded or drawn metal tube. On the first plan the inner edge of the coil should be kept in place with a small rivet. Or the tube and its base may be punched up in dies out of a disc of metal all in one in the way already known and practised. Or the tube may be made of a length of metal tubing having a metal disc soldered or brazed on one end as the base.—Patent abandoned.

1380 W. M'KEAN, Paisley. *Cattle food.* Dated May 5, 1869.

The glutinous, fatty, and other components of the grain remaining after the usual more or less complete separation of the starch are collected and drained, and the mixture thus obtained is put into cloths or bags which are laid in shallow boxes, trays, or frames, to give them a suitable form. The mixture in the cloths or bags is then submitted to severe pressure in any convenient press, boards or metal plates being placed between the bags at intervals; and the pressure not only expresses the moisture almost entirely, but also causes the material to adhere together in the form of a solid cake. The cake thus obtained is finished by drying or baking it in a stove or oven, and is then ready for sale.—Patent completed.

1381 E. H. RICHMOND, King William-street, E.C. *Preserving meat.* Dated May 5, 1869.

The vessel for preserving the meat consists of a rectangular or other shaped tank or vessel formed of plates of galvanised iron. The sides of the tank are perforated, and the top and bottom plates are formed solid, an opening or manhole being left through the top of the tank for access to the inside, which is fitted with two, three, or more rows of shelves fixed to two opposite sides of the tank, and extending from end to end thereof. The inventor proposes to fix the shelves one above the other about 4ft. apart, leaving a clear space between them in the middle of the tank for the persons to stow away the meat that is to be preserved.—Patent abandoned.

1382 A. COCKE, Water lane, E.C. *Carriage ventilators.* Dated May 5, 1869.

The inventor forms gratings or other passages, by preference around the roof lamps, for the escape of air from the compartment, and surrounds such passages with a shield, over which he applies a cowl capable of turning on a centre, so that the outlet thereof may be contrary to the direction of motion of the carriage or of the wind, but this cowl, in place of fitting near the lower edge thereof to the shield, is opened out at the part thereof opposite to the outlet therefrom in order that air may freely flow through the cowl. The lower part of this cowl overhangs the shield to an extent sufficient to prevent rain passing in that direction.—Patent completed.

1383 H. HIGHTON, Brighton. *Making artificial stone.* Dated May 5, 1869.

The inventor uses for the purpose of making artificial stone, sand and gravel made artificially by crushing granite or other hard stone by Blake's or other suitable mechanical stone crushers, by which the surfaces of the sand and gravel are left rough and the edges sharp and angular.—Patent abandoned.

1384 C. MOORE, Sketty, Swansea. *Screw propeller.* Dated May 5, 1869.

This consists in the peculiar formation and action of a double-threaded screw propeller for ships of half a convolution, which is brought to a body at the propelling shaft between the forward and aft sternpost. The leading edges of both threads or blades are formed to join in the centre of both ends of the said shaft and form a closed curved line curling in opposite directions. The threads or blades themselves are concave and convex on each surface, balance each other, and are shaped in such a manner that the chief propelling surface of each falls towards the lines of junction, and that the streams of water thrown off by the propeller diverge, thereby preventing churning of the water near the centre of motion, and always leaving the rudder in comparatively quiet water.—Patent completed.

1385 C. J. GALLOWAY and J. H. BECKWITH, Manchester *Steam valves.* Dated May 5, 1869.

This refers to letters patent dated July 14, 1868 (No. 2221). The inventors connect the arms by means of a rod. to a piston, fitting accurately into a cylinder containing oil or other fluid, which piston has one or more apertures through it, through which, when the piston is moved backwards or forwards by the motion of the arm, the fluid will be caused to pass from the one side of the piston to the other. By this means the piston, in whatever position it may be, will offer considerable resistance to any motion being imparted to it, unless such motion is of a very slow nature, such as it receives from the governor.—Patent completed.

1386 J. E. PHILLIPS, Grantham. *Sewing machines.* Dated May 5, 1869.

This relates, first, to that class of sewing machines in which a revolving shuttle is employed. The inventor employs two shafts or axes one above and one below the cloth plate of the machine, and gives motion thereto by means of toothed pinions fixed on the ends of such shafts or axes and driven by a toothed ring or wheel, as is now common with some descriptions of sewing machines, upon the end of the lower axis. He fixes a revolving shuttle carrier at the back of the shuttle driver, employs a cam to give motion to the feed lever. By this arrangement a superior hand machine is obtained.—Patent completed.

1387 R. H. RAY, Saffron Walden. *Reaping and mowing machines.* Dated May 5, 1869.

Reaping and mowing machines are fitted with two sets of knives in order that the grain or grass may be cut while the machine is travelling up or down the field. The frame of the machine is constructed preferably of iron of I-shape in section; it is formed with an opening for the main bearing wheel to work in. The main bearing wheel is of sufficient width for all or nearly all of the driving mechanism to be enclosed within it.—Patent abandoned.

1388 T. WELTON, Grafton-street, S.W. *Curing by gaseous charcoal.* Dated May 5, 1869.

The inventor takes charcoal, either animal or vegetable as may be found most suitable, and grinds it into a powder or such sized piece as may be requisite and puts it into a proper vessel. He heats it and by so doing expels the atmospheric air; he then admits to it while so heated such gas as may be required, or a mixture of gases or vapour of metal or metals or drugs or vapour of phosphorous bromine, ammonia, iodine, or other materials, which the charcoal by a well-known law will then absorb in various quantities according to the gas and the other named materials used. Such charcoal when so prepared may then be used as a dentrific or cataplasm or anæsthetic, or for other curative purposes.—Patent completed.

1389 E. N. HUDSON, Percy-terrace, Bayswater. *Velocipedes.* Dated May 6, 1869.

The inventor forms a framed carriage, the lower parallel sides of which have bearings in the after part thereof resting upon other suitable bearings of a crank axle running through and rigidly connected with the two driving wheels of the carriage. He then forms in the fore part of the carriage a socket through which he runs a forked bearing for the purpose of holding the guiding wheel of the vehicle by a short axle through the box or centre thereof or by other suitable attachments, while the steering of the vehicle is effected and managed by means of a transverse crosshead, bar, or key pivoted on and attached to the top of the forked bearing.—Patent completed.

1390 H. E. NEWTON, Chancery-lane. *Enlarging drawings, &c.* (A communication.) Dated May 6, 1869.

The apparatus consists of a suitable framework or table, on the top of which are grooves which form guides for four sets of small wheels or rollers destined to carry two horizontal rectangular platforms or drawing boards, on which the drawing or basso-relievo to be enlarged or diminished is placed. At one end of the machine, but in the centre of its width, is mounted a vertical spindle having its bearings in the cross pieces of the framework. The lower part of this spindle is enlarged so as to permit of a vertical slot being cut in it to receive one end of a short connecting rod (the other end being pivoted to a motor wheel by a ball and socket joint) which is held there by means of a pin or bolt.—Patent abandoned.

1391 C. D. ABEL, Southampton-buildings. (A communication.) *Manufacture of iron.* Dated May 6, 1869.

This consists in mixing with molten cast iron pulverised carbonaceous matter either alone or together with pulverised oxides in such proportions and in a such a manner as to produce at once a solid conglomerate mass of such cast-iron and carbonaceous matter, which is then treated in a furnace either with or without the addition of oxidising substances for the production of either wrought-iron or steel therefrom.—Patent abandoned.

1392 J. TOLSON, Dalton, Huddersfield. *Carding cards.* Dated May 6, 1869.

This relates to letters patent dated January 30, 1869, and consists in the application to the cleaning apparatus of a roller clothed or covered with either cards, felt, or some other material of a soft, yielding, or elastic nature, the roller to be turned round by suitable gearing from the cleaning apparatus or the power which gives motion to the comb cylinder (or other cleaning apparatus), the roller being caused to rest and press upon, and by such contact communicate rotary motion to, the card cylinder or card roller of a carding engine required to be cleaned.—Patent completed.

1393 W. BENNETT, Aston, and J. CURRALL, Birmingham *Kitchen ranges.* Dated May 6, 1869.

This consists, first, in giving to the bottom of the grates of kitchen ranges a rising and falling motion by means of a vertical screw, which also raises and lowers the ash pan at the same time. Second, in giving to the bottoms of the grates of kitchen ranges a rising and falling motion by means of racks on the sides of the grate. Third, of a box or hollow chamber placed on the top of the fall-bar of the grate. Fourth, of the following arrangement of the parts of a kitchen range for cottages and small houses. The range consists either of an oven on one side of the fireplace and a boiler on the other, or an oven on each side, or an oven only on one side with a sham oven on the other side. Fifth, of a rising and falling dust preventer, serving also as a stand or table. Lastly, of a draw plate or blower somewhat similar to the ordinary draw plate in form, but provided with a button or turn by which it can be fixed to the back plate of the grate.—Patent abandoned.

1394 I. and G. BATTINSON and T. WHITEHEAD, Halifax. *Combing wool.* Dated May 6, 1869.

The inventors impart to the rollers and leather belt or apron a rising and falling motion so that a constantly changing surface or part of such belt or apron is presented for the passage of the wool or fibre. The formation of a groove or channel is thus prevented, and the belt or apron works evenly over its whole surface. This is effected by use of the apparatus constructed as follows:—The spindles of the two fluted or drawing-off rollers are elongated, and at the foot of one is a gear wheel for giving motion thereto. On the spindle of the outer fluted roller, and about midway between the bottom of the roller and the gear wheel, is a collar resting on an eccentric. The eccentric is on a cross shaft worked from the "noil" shaft or other convenient part of the machine. As the eccentric revolves, it lifts or raises the outer spindle and roller thereon. The other fluted roller over which the belt or apron works is provided with collars or flanges extending over a portion of the diameter of the outer roller, on the upper end of which the collar or flange rests, so that, as the outer spindle and roller is raised, it at the same time raises the other fluted roller and the belt or apron thereon. The eccentric having passed its highest lift the spindles, rollers, and apron descend by gravitation, and by the eccentric acting on a second collar.—Patent completed.

1395 W. GALLOWAY, Craigie. *Railway brakes.* Dated May 6, 1869.

This consists in attaching a pipe to a cylinder connected with the boiler of the engine which draws the train, or to a vessel or receiver in which air and water are compressed to the required extent. At a convenient position on the carriages composing the train, cylinders having pistons in them are situated. These are in connection with the pipe hereinbefore referred to, the pipe extending throughout the train. To the piston rods of the several cylinders are coupled the links for actuating the brake blocks.—Patent completed.

1396 W. GALLOWAY, Craigie. *Communicating in trains.* Dated May 6, 1869.

This consists in carrying a pipe from the engine, which pipe extends throughout the train of vehicles. Suitable couplings or joints are formed at the ends of the pipe at the extremities of each carriage, so that they can be with facility connected or disconnected. To the engine which draws the train a cylinder with a piston in it is attached. The spaces in the cylinder on one or both sides of the piston are filled with water, and water also fills the pipe throughout the train. In the compartments of the carriages means for opening cocks or valves connected with the pipe are situated, so that on opening any one of the cocks or valves some of the water is forced out by the piston, thus diminishing the quantity of water throughout the pipe, and enabling the pressure of the steam in the boiler acting upon the upper or one side o the piston to depress it.—Patent completed.

1397 J. NEEDHAM, Chiswick. *Velocipedes.* Dated May 6, 1869.

The inventor carries the seat upon a fulcrum so as to constitute a lever, and he connects thereto either in front or behind two rods passing down and connected at the lower ends to the cranks or treadles.—Patent abandoned.

1398 G. KENT, High Holborn. *Refrigerator.* (A communication.) Dated May 6, 1869.

The inventor constructs a box inside of which he places another box, the inner box being sufficiently smaller than the outer one to allow of an air space around the sides, ends, and bottoms of the inner box, the sides of which are covered with wool, felt, or other non-conductor. The whole is then lined with zinc, galvanised iron, or other appropriate material, and made watertight, thereby forming a receptacle within which to place the article to be preserved.—Patent abandoned.

1399 J. M. HART, Cheapside. *Strong rooms and safes.* Dated May 6, 1869.

This relates, first, to means of constructing safes or depositories for security, and to the construction of parts of locks. Second, to means for securing the door to the frame of safes or depositories, strong rooms, and such like places when locked, and for resisting the tendency to warping of the parts under extreme heat or otherwise.—Patent completed.

1400 G. T. BOUSFIELD, Loughborough Park, Brixton. *Braces.* (A communication.) Dated May 6, 1869.

This invention is based upon the discovery that suspender ends can be constructed of strong felt or cloth so firmly fitted that it does not ravel when cut, without the necessity of binding or turning in the cut edges, and that the articles produced are free from the defects of the older kinds of suspender ends above referred to, this new manufacture of suspender ends being attended with the following advantages, viz., the articles can be cut by means of dies to any desired form, they do not ravel at the cut edges, and therefore do not require the edges to be bound or to be turned in and sewed, they do not smell offensively, nor stretch, as india-rubber web suspender ends do, they do not stain the clothing, nor become discoloured or stiff.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated November 16, 1869.

3299 G. Cherpit, Manchester. Improvements in the construction of healds for looms.

3300 W. H. Tucker, Southampton-street, Strand. Improvements in locks.

3301 W. Lancaster, Manchester. Improvements in furnaces for steam boilers and other purposes.

3302 W. Srigley, Burbage, near Buxton, Derbyshire. A friction engine, whereby motive power is produced.
3303 M. Sautter, Rue de la Chaussee d'Antin, Paris. Improved reloading cartridge shell.
3304 H. H. Violet, Tours, department of Indre et Loire, France. Improvements in adherent stoppers, applicable to every species of bottle.
3305 C. Asbury, Balsall Heath, Worcestershire. Improvements in steam boilers.
3306 J. G. Garrard, Bishop's Stortford, Herts. Improvements in the construction of buffers adapted for railway carriages and other vehicles, and as a substitute for weight springs used therewith, and for checking the recoil of heavy guns.
3307 W. Niell, jun., Bold, Lancashire. Improvements in blast engines.
3308 J. Oppenheimer, Manchester. Improvements in fixing and staying telegraph posts.
3309 F. Delacroix, Boulevard de Strasbourg, Paris. An improved metallic manometer.
3310 C. Ching, Castle-street, Long Acre. Improvements in the boilers of hot water apparatus for supplying baths and other purposes.

Dated November 17, 1869.

3311 P. Negrin, Marseilles, France. An improved arrangement for regulating the flow of liquids through pipes, valves, cocks, or other conducts.
3312 S. J. Mackie, Kensington. Improvements in the construction and propulsion of floating vessels.
3313 J. Crofts, R. Dawson, and J. King, Hunslet-lane, Leeds. An improvement in apparatus for combing wool or other fibres.
3314 T. Marshall, Clyde-place, Glasgow. A composition for the prevention of fouling of ships' bottoms and other articles in continuous or frequent contact with water, which is called ships' anti-fouling composition.
3315 T. and H. Weston, Birmingham. Improvements in the manufacture and coating or casing of metallic tubes and rods.
3316 J. Willis, Stocksbridge Works, near Sheffield. Improvements in the manufacture of umbrellas.
3317 E. Bazin, Angers, Maine et Loire, A. Ruiz, Rue d'Argenson, and E. Le Pelletier, Rue Lepic, France. Improvements in spinning looms, and in the spindles employed therein.
3318 W. H. Perkin, Sudbury, Middlesex. Improvements in the manufacture of colouring matter suitable for dyeing and printing.

Dated November 18, 1869.

3319 K. Ogden, Manchester. An improved deodorising receptacle or sarcophagus for containing dead bodies or coffins having bodies therein.
3320 G. R. Sweetser and G. Wadman, Essex-road, Islington. Improvements in machinery for working wood.
3321 G. B. d'Adelsward, Boulevard Bonne Nouvelle, Paris. An improved apparatus for taking, still hot, the dross out of high furnaces.
3322 J. Woodward, Queen's Foundry, New Islington, Ancoats, Manchester. Improvements in gas and water or other liquid meters.
3323 E. Korting, Oakley-road, Islington. Improvements in apparatus for feeding boilers and for raising and forcing fluids generally.
3324 C. Faure, Strand. Improvements in galvanic batteries.
3325 J. P. Kerr and W. M'Gee, Paisley, Renfrewshire. Improvements in apparatus for winding thread or yarn upon pirns.
3326 G. H. Kenworthy and T. Knowles, Ashton-under-Lyne. Improvements in machinery or apparatus for preparing cotton or other fibrous substances for carding.
3327 M. Shelley, Georges-square, Hoxton-square, Hoxton. An improved vent peg for preserving liquors of all kinds.
3328 H. A. Hammond, Cannon-street, City. An improved chimney cowl.
3329 G. Petrie, Rochdale. Improvements in the preparation of ashes for the manufacture of manure, and in the separation of cinders therefrom, which improvements are also applicable to the preparation of materials used in the manufacture of bricks and tiles.
3330 T. Llewellyn, Great Portland-street. An improved construction of cutter applicable to the squaring, planing, grooving, and rabbetting of wood.

Dated November 19, 1869.

3331 S. Mendel, Manchester. An improved mode of packing bales of cotton and other fabrics.
3332 J. Dockray, Quebec Foundry, Leeds. Improvements in machinery for drying, dressing, and finishing thread, twine, cords, and ropes.
3333 J. Hartley and Z. Sugden, Halifax. Improvements in wrought-iron boilers for hot water apparatus.
3334 T. E. Lundy and J. L. Dunham, City-road. New or improved means of communication between passengers in cabs, private carriages, omnibuses, tramroad cars, and other such like vehicles, and the drivers or conductors thereof.
3335 G. F. Cornelius, Great Queen-street, Westminster. Improvements in the manufacture of paint and varnish.
3336 R. Clews, Dundee. Improvements for weaving textile fabrics.
3337 R. K. Miller and A. B. Herbert, Edinburgh. Improvements in pumps.
3338 J. Orson, Glasgow. Improvements in machinery or apparatus for goffering and plaiting textile fabrics.
3339 W. N. M'Cartney, Glasgow. An improved railway carriage for passengers.
3340 W. and M. Bayliss, Cannon-street, City. Certain improved means for making or producing cast-iron earth screws for the lower parts of fence, telegraph, and other posts or supports, and which said improvements are also applicable for other purposes.
3341 A. M. Clark, Chancery-lane. An improved revolving battery gun.

Dated November 20, 1868.

3342 I. Hayford and J. F. Paul, Boston, Suffolk, Massachusetts, U.S.A. Certain improvements in the mode of laying or constructing wooden pavements for streets, &c., as well as a new and useful process for preparing wood for pavements.
3343 W., J., and F. W. Edmondson, and R. Cunliffe, Manchester. Certain improvements in machinery for engraving cylinders used in printing.
3344 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the means and apparatus for utilising streams, subterranean and other springs, lakes, ponds, and other surface waters, as motive power.
3345 J. Cochrane, Grange, Stourbridge, Worcestershire. Improvements in pipes, tubes, or conduits for the conveyance of letters, parcels, and other objects by pneumatic agency.
3346 H. Wilson, Stockton-on-Tees, Durham. Improvements in lubricating apparatus for steam engines, steam hammers, and other mechanism in which steam is the motive power.
3347 B. Guiseppe, Milan, Italy. A new cylindric vertical boiler for the formation of the steam and for heating of the water for maintaining the same boiler.
3348 L. Folliet, Rue Feydeau, Paris. A new grease box called Folliet's grease box.
3349 J. Taylor, Wigan, Lancashire. Improvements in the construction of furnaces.
3350 J. Belicard, Manchester. Improvements in the manufacture of metal healds for weaving.
3351 T. Aitken, Irwell Vale Mill, Helmshore, near Manchester. An improvement in washer cloth to be used in spinning or similar machinery.
3352 W. Temlett, Union-street, Borough, Surrey. Improvements in banjos and certain other stringed instruments.
3353 T. R. Hetherington, Manchester. Improvements in machinery for preparing, spinning, and doubling cotton and other fibrous materials.
3354 D. Morgan, Burntisland, North Britain. Improvements in the manufacture of lubricating oil or grease.
3355 T. F. Lynch, Aldersgate-street, City. Improvements in bottles for holding poisons and other preparations.
3356 S. H. Salom, Regent-street. An improved apparatus or instrument for clipping or shearing the hair of horses and other animals.
3357 A. B. Childs, Mark-lane, City. Improvements in machinery for cleaning, scouring, and decorticating wheat and other kinds of grain, and also for hulling, cleaning, and polishing rice.
3358 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for distributing type.
3359 J. H. Fraser, Bromley-by-Bow. Improvements in boilers.
3360 S. L. Loomis, South Byron, Tennessee, New York, U.S.A. A new, useful, and improved sash tightener and holder.
3361 Sir J. Macneill, Kensington. Improvements in lucifer match and fusee boxes or cases, and in frictional surfaces for igniting lucifer matches and fusees.
3362 J. Moseley, Newcastle-upon-Tyne. Improvements in the mode of warming feet, and in apparatus for this purpose.
3363 J. Burroughs, jun., Newark, New Jersey, U.S.A. Improvements in electro-magnetic machines, and in magnets for the same, and for other purposes.

Dated November 22, 1869.

3364 R. Wilson, Patricroft, near Manchester. Improvements in the construction of hydraulic presses and other hydraulic machinery.
3365 S. W. Wilkinson and J. E. Dooley, Stockport, Cheshire. Improvements in the construction of pillar post office and other stationary or portable letter boxes and bags.
3366 G. H. Wilkes, Campbell-terrace, Wick-road, South Hackney. Supporting clothes' lines.
3367 J. Bourne, Birmingham. Improvements in gauges for gauging the water in steam boilers, and for other like purposes.
3368 J. Bottomley, Bradford, and S. Emsley, Oakenshaw Mills, Low Moor, near Bradford, Yorkshire. Improvements in spinning fibrous substances.
3369 J., J., and H. Ingham, Thornton, near Bradford, and C. Smith, Horton, near Bradford, Yorkshire. Improvements in shuttles for weaving.
3370 R. Hennell, Sussex-gardens. Improvements in the construction of pavements for streets, bridges, and other places, and in the means of taking up such pavements with facility.
3371 F. Hawkings, Harrow-road. Improvements in fire-escapes.
3372 G. Ritchie, Tyrwhitt-road, Lewisham-road, Kent, and J. Ritchie, Stonefield-street, Barnsbury. Improvements in tents, weather protectors, sunshades, and umbrellas.
3373 J. Thomlinson, Abbey-street, Carlisle. Improvements in the manufacture of cements.
3374 J. Brooks, Sherlock-street, Birmingham. Improvements in fastenings applicable to ladies' stays, gloves, boots, and other similar articles.
3375 E. E. Allen, Pelham-place, Brompton. Improvements in the construction of tramways, and in engines and carriages employed thereon.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," November 23, 1869

2058 J. Wright
2077 J. Gessert
2080 C. L. Caldesi
2085 J. Bannehr and H. Matthews
2093 C. A. Bates
2098 C. D. Abel
2100 E. Pettitt
2109 W. P. Bain
2111 R. Craig
2120 T. Richards
2131 G. Lowry
2135 C. de Bergue
2143 J. E. Millar
2152 R. B. Evered and R. Hurst
2155 P. Murray

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, DECEMBER 3, 1869.

NEW PORT ON THE FRENCH COAST.

THAT the present ports of Boulogne and Calais are little better than useless for the purpose of shelter in bad weather, is known to everyone who has crossed the Channel. The story is still fresh in everyone's mind of the English mail steamer that left Dover, and, after ineffectual attempts to enter either of the harbours of Calais or Boulogne, was compelled to return to the shore from which she started. So much for French marine engineering. Nor is our own much better. It is no less true than disgraceful that of all the branches of the profession, that relating to harbours is the most backward. Look at the gigantic failures that have been perpetrated, involving an enormous waste of money! There is no fault to be found with the constructive details—they are right enough; but the plain fact is, that we build harbours which are sources of actual dread to the mariner rather than of protection. The perils of a voyage, long or short, are frequently nothing to those of "getting the ship in." With the view therefore of establishing a port on the opposite side of the Channel which shall be in reality a port of refuge, a valuable contemporary informs us that there is a project on foot, by the company of Waring Brothers, to build a harbour at Audresselles, a place about a couple of miles from Cape Gris-Nez. This harbour is intended to shelter any vessel, whatever water she may draw, and the plans have been laid before the Minister of Public Works. It will be readily imagined that the inhabitants of those marine towns which have so long enjoyed a monopoly of John Bull's patronage and money are dead against the scheme. They have accordingly memorialised the Minister on the subject, alleging, in terms of bitter remonstrance, that the establishment of a port at Audresselles would entail ruin upon their own commerce and general misery upon his Majesty's subjects in those parts. In their opinion, the closing of our dockyards and the Admiralty reductions are nothing to it. While, on the one hand, there is not the slightest doubt that his Majesty is willing to listen to the complaints of his subjects, yet, at the same time, they must base their case upon something better than mere self-interest. It will not do to request that a concession be refused to an English firm to establish a port at a certain place merely because it will interfere with the traffic carried on elsewhere. One of two circumstances must be demonstrated—either that the proposed work is unnecessary, or that it is inadequate. Let us see if the memorialists can make out their case, and in the first place take a glance at the navigation of the opposite coast.

In stormy and tempestuous weather, ships navigating the shores in question make for the open sea, a general statement which speaks volumes for the state of the French harbours. Should the change be so sudden that they have not time to "run for it," they endeavour to beat up for the harbour of Boulogne, supposing the storm to be from the south, west, or south-west. If the wind is from the opposite quarters, they must try and make for Calais. As a rule, therefore, one or other of these ports is generally accessible, at least according to the evidence of the French captains, who, on the other hand, assert that the harbour at Audresselles could not be reached in stormy weather by any ship without her incurring the danger of striking upon the rocks surrounding Cape Gris-Nez, or going to pieces among the numerous reefs in the locality. The interested inhabitants of Calais and Boulogne remark, moreover, that the establishment of a port at Audresselles would lure vessels to their destruction, as the captains and skippers would make the attempt to enter, rather than put to sea. Again, the prevailing winds in the Channel are unfavourable to the situation of the proposed harbour—a point which, if true, ought to be held fatal to the intended scheme. This portion of the memorial is confined to a consideration of the question on the grounds of security of navigation, which are founded upon the observation of the winds and other local meteorological phenomena, the configuration of the coast line, and the geographical position of Audresselles itself. It also petitions for a rejection of the scheme, since, without affording any real protection in times of tempest, it holds out a delusive hope to those who may be rash enough to trust to it. It must be admitted that the memorialists have not allowed the grass to grow beneath their feet. But there is another view to be taken of the matter which more particularly touches the inhabitants of the existing ports. They are afraid that the term "port of refuge" is only a pretext to hide the real character of the project, which is to establish a "port of commerce" on French territory. This fear has its origin in one of the clauses proposed by the company, in which it is stated that the quays are to be reserved exclusively for the use of the monster packet boats which it is the object of the company to establish. It is for the Imperial Administration to decide whether this would be for the material advantage or disadvantage of the two nations, at the same time that due regard is paid to existing interests. If, however, the position of Audresselles is such that it is calculated to serve as a real port of refuge, it cannot be denied that the French coast is greatly in want of it, and the sooner it is built and tenanted the better for ourselves and our neighbours also.

THE BRITISH ASSOCIATION AND THE SEWAGE QUESTION.

THOSE who are the least acquainted with the operations of the British Association are aware that in many departments of applied science it has long been, and is still, doing good work. It is now giving practical attention to the all-important question of the treatment and utilisation of sewage. At the meeting of the Association at Norwich a grant of £10 was made to enable a committee to collect preliminary information. This work having been effected, and reports having been obtained respecting the methods of dealing with town refuse practised in most civilised countries, the committee was reappointed at the meeting of the British Association this year at Exeter. The importance of the inquiry led to a further grant of £50 being made towards a fuller investigation of the subject. We need not remind our readers that £50 is a mere trifle, and utterly inadequate to the prosecution of an inquiry of such magnitude and importance. But the British Association is a purely scientific body, and has no funds at its disposal applicable to the purpose, or adequate to its requirements. It is, however, important that the committee should take advantage of the opportunity thus created by the British Association to investigate the entire subject in all its bearings—whether chemical, physiological, or engineering, sanitary, municipal, or agricultural—and in a manner worthy of the body they represent. As far as personal services are concerned, the committee freely and generously offer these. But in order to properly carry out such an inquiry with a practical end, numerous observations, experiments, and analyses are essential. These cannot be accomplished—especially the analyses—without the aid of efficient and highly-paid assistants. Besides, the committee will, no doubt, find themselves obliged to purchase expensive apparatus, and to practically investigate any proposed improvements which may be brought under their notice. To do all this well and properly funds are unquestionably necessary, and having no source whereon to draw, the committee have circularised the municipal authorities of the various towns in Great Britain and Ireland, asking for subscriptions towards this important object. This circular letter will be found on another page; in it the committee suggest a contribution of £5 5s. where the population does not exceed 10,000, between that number and 25,000 £10 10s. is suggested, from 25,000 to 50,000 they name £21, and so on *pro rata* for every increase of 25,000 of population.

We earnestly call attention to this matter, and urge upon the public the necessity of helping—each in his degree—to promote this important investigation, which we may be sure will be properly pursued. The names of the gentlemen who have kindly consented to act upon the committee are a guarantee for this; these names will be found appended to the circular to which we have referred. We trust the committee will be well supported in their endeavours to elucidate a question presenting such important features of social and scientific interest. They desire, not only to ascertain, as far as possible, the causes of the sanitary inefficiency of existing works, but also to inquire into every suggestion which affords promise of practical utility, in order that this investigation may be searching, the report practical, and any recommendations that may be made authoritative. At the present time it is of the first importance that a full and complete investigation of the question should be made by the light of the knowledge and experience now gained in the several departments of chemistry, physiology, and engineering. We commend the suggestions of the committee to the municipal authorities, not doubting that they will see the wisdom and policy of giving a generous response to the appeal, and in heartily aiding by all means in their power to promote the good end which the investigation has in view, viz., the health and welfare of the nation.

TRIAL OF THE "DRUID."

THE fact of the "Druid" gunboat having recently had a trial was referred to by us last week in connection with the narrow escape that vessel had from disaster on account of her compass refusing to act. We now purpose noticing the trial itself and its results. The "Druid" has not yet come into the hands of Government, so that the run in question was only a contractor's trial. But it was invested with a special interest in consequence of the Admiralty authorities having directed that it should be regarded as a competitive trial to test the merits of the Griffiths propeller as against those of the Vansittart (late Lowe) propeller. The "Druid" is fitted with the Griffiths propeller, and the trial of the Vansittart propeller was to follow. The result of the competition is looked forward to with much interest, as Mrs. Henrietta Vansittart is the daughter of the late Mr. Lowe, who, so far back as 1838, introduced the system of screw propulsion to the notice of the Admiralty. Since her father's decease Mrs. Vansittart has devoted herself to the task of perfecting the invention. A few months ago the Vansittart propeller was tried on board the "Cadmus," one of the corvettes attached to the flying squadron, but the accident which happened to that vessel on her voyage down Channel forbade the further prosecution of the test at that time. Hence the permission of the

Admiralty to renew the test with the "Druid," a similar class of vessel. The engines and boilers of the "Druid" are by Messrs. Maudslay, Sons, and Field; the former being constructed on the horizontal principle, with jacketed cylinders, and having surface condensers. The boilers are four in number, with 16 furnaces, the boilers being fitted with super-heating apparatus, with flattened tubes, so that, as arranged, the engines can be worked with super-heated steam or not. The screw, as before stated, was a Griffiths, having been manufactured by the firm above-named. The diameter is 15ft.; the pitch was 15ft. 2in., length 2ft., and the immersion of the upper edge, 6in.

On the present occasion the "Druid's" draught of water was 12ft. 9in. forward and 16ft. 4in. aft. The ship was fully rigged, and had all her guns, about 300 tons of coals, besides other stores, with a large quantity of iron ballast on board, together with about 200 officers and men. The sea was smooth, and the force of the wind from 1 to 3. Six runs were made at full boiler power, giving an average of 12·98 knots; at half boiler power the average was 11·29 knots —the average number of revolutions per minute being 96 50. This was within a fraction of the estimated speed of the vessel. On making the circles the "Druid" proved herself a very handy ship, answering her helm in the readiest manner. Thus, so far as the engines and ship were concerned, everything was satisfactory; but it was found almost impossible to retain the necessary supply of steam, as the boilers primed badly, as they had done on a previous occasion, when the fires had to be drawn. Besides this, the "Druid" was found to vibrate to an unusual extent during the runs at full boiler power. At half-boiler power—which is commonly supposed to be the usual power employed on ordinary occasions while cruising—the vibration was not so severe, although then very palpable. There can be little doubt about the result of this unsatisfactory state of things—the influence of this vibration must rapidly tell on the vessel. Three months at sea would necessitate a regular overhauling and repair in the dock. We await the trial of the Vansittart propeller, and shall then place the results before our readers for comparison with those of the Griffiths screw as given above.

MANUFACTURE OF INDIAN INK.

A VERY large proportion of our readers are probably in the habit of using what we term Indian ink, or, at any rate, have used it during some portion of their lifetime. The term, although very ancient, is a complete misnomer. That employed by the French, *encre de Chine*, is the more correct and the one which has some tangible reference to the country whence this indispensable accessory to the drawing office is exported to our shores. A brief account of the method of manufacturing it in the ancient land of Kathay will not be without interest, the more especially as all attempts to prepare it of an equal quality, in this country or on the continent, has altogether failed. In times so remote as almost to carry us back to the ages of fable, the Chinese executed their specimens of caligraphy through the agency of a piece of bamboo dipped in a kind of black varnish. Subsequently, while the same *stylus* was retained, the liquid was represented by a syrupy fluid, in which particles of a black stone reduced to an impalpable powder were held in mechanical suspension. Later still, the ink assumed the appearance and nature of solid black balls, prepared from lampblack, and ever since their introduction this branch of industry has been gradually improved until it attained its present state of perfection. At the present day, the Chinese keep their ink in sticks, rub it with water or tea, and write by means of very fine pointed pencils dipped in it. The quality of the ink varies considerably, and depends upon the purity of the ingredients of which it is composed, and the care and skill displayed in its preparation. Among the best substances from which to obtain the lampblack are—firstly, pig's fat; secondly, ordinary oils and fats; and thirdly, resinous woods and resins themselves.* Tolerably good inks are also made from the lampblack produced by the combustion of pine trees, and some other descriptions of timber indigenous to the country.

The materials from which the lampblack is procured are placed in a furnace about a hundred feet in length, and five in breadth, along the sides and top of which it condenses. That which condenses at the extremity of the furnace is the best adapted for the manufacture of the ink, while the rest, which is deposited near the neighbourhood of the combustion, is too coarse in grain to be employed for the purpose. This evidently results from two causes. One is the quality of the material, and the other the relative rapidity with which it is consumed. Having obtained the lampblack, the next step is to prepare a particular kind of paste or glue with which to form a compact and solid substance. The preparation of this glue requires a great deal of care, and is one of the most important operations connected with the whole process. The best description is made from the horns of deer. After removing the outer skin, the horns are macerated for a period of seven days in rice water, and then subjected to a long and exhausting ebullition. It is only during the cold season of the year that this process is carried on, as hot weather would cause the fermentation of the glue and retard the operation. It must not be imagined that the lampblack is fit for use directly it is taken out of the furnace. On the contrary, it requires to be sifted through silken bags, so that the grains may all be of the same size, or otherwise the ink would not be homogeneous. This preliminary condition being ensured, a certain quantity of the glue is melted and poured over an equal quantity of the other ingredient, and the whole thoroughly kneaded and incorporated by the hands. Occasionally a small portion of Chinese varnish is added, and the mixture transferred to an iron mortar, where it is beaten up with some degree of violence. The whole of the value of the future product depends, as is usual in all similar instances, upon the intimacy of the mixture, but, at the same time, the operation must not be protracted to too great a length. It is the duty of the manufacturer to time the process, and when, through negligence or ignorance, the proper time has been exceeded, the error is rectified by enveloping the ink in paper, and holding it before a slow fire, which restores to it its elasticity, and prevents it splitting. In spite, however, of this partial remedy, the ink so treated is never equal in quality to that which has not been subjected to such treatment. From the mortar the mixture passes into the hand of the moulder. The moulds are formed of wood, with a cavity corresponding to the form it is desired to give to the ink. Within certain limits the smaller the cakes the better, as there is less chance of their splitting or warping during the time they are drying. Thus, the best cakes of Indian ink are never of a very large size. As soon as the cakes have acquired a firm and solid consistency, they are removed from the moulds and dried. The desiccation is effected by enveloping the ink in very fine paper, and surrounding it by cinders or powdered chalk. When the latter desiccator is used care must be taken that it does not abstract the humidity from the cake with too great rapidity, or the latter will become brittle, and lose its superior quality. The cakes, together with the absorbent envelopes, are placed in a small stove, and kept exposed to a gentle heat for several days. Some manufacturers do not take the trouble to perform this last drying process, but leave the cakes to dry by simple exposure to the air.

* For a full account of this process see an excellent work by M. Paul Champion, "Industries Anciennes et Modernes de l'Empire Chinois."

The author of the work to which we have alluded gives some practical suggestions for distinguishing good from bad Indian ink, which will, we do not doubt, be very acceptable to our readers. Ink of a superior quality rubs easily and marks upon paper, without leaving any apparent trace of solid matter. The best cakes have a brownish hue when rubbed. A black, grey, or blue tinge indicates ink of an inferior quality. The brown tinge will remain in cakes for many years after manufacture, and is visible in some very ancient specimens that exist in China. Another somewhat curious test will determine the quality of Indian ink. If a ca e of good quality be struck gently on a hard substance, the sound should be sharp. If it be flat, it is a sign that it is not homogeneous in consistency, and belongs to second class description. Moreover, the heaviest ink is the most valuable. The Chinese say that the value of lampblack depends upon its lightness, and that of ink upon its heaviness, being in the inverse ratio one to the other. As the ink gets older, so, like wine, it improves in quality. It becomes harder without at the same time becoming brittle, and acquires a brilliancy that is highly prized by connoisseurs. Strictly speaking, it ought not to be used for three years after manufacture. Whenever it happens that old ink loses its value by absorbing damp, it may be re-prepared by grinding it with a mixture of glue and water, but the operation is not always successful. In order to keep Indian ink—in other words to preserve it—it should be placed in a well-aired situation, exposed now and then to the action of the sun, and rubbed frequently on the surface to prevent it losing its polish.

The manufacture of Chinese ink, to give it its proper term, is carried on upon a very large scale at Shanghai, where a very superior description is prepared. The cause of the difference in quality between the various inks made in China results from the non-employment of a constant material for the production of the lampblack. In order to impart an agreeable odour to the production, the Chinese add a small portion of musk and camphor, from the Isle of Borneo, two articles which are exceedingly dear in the celestial empire. Ordinary Chinese ink for home use is not scented in any manner whatever. The gilded mystic letters that are so attractive to young pupils and students are first formed by the action of the mould. When the cake is dry, the letters are traced over with a solution of gelatine in water, and the gold or copper is laid on with a fine brush. Like their neighbours, the Japanese manufacture Indian ink, but consider it of a quality inferior to that which they obtain from the mainland. Not having given so much attention to the matter as the celestials, they are not so well versed in the manner of preparing the lampblack, which is the real secret of the whole art.

NOTICES OF BOOKS.

IT will be no new thing to our readers to be informed that some of the most beautifully delicate and elegant figures can be produced by the lathe. But it will be new to them to learn that a volume of such figures —and nothing else—has been published. And yet this is the case, and well worthy of notice they are for their variety and beauty. The little volume before us* consists of thirty exquisite photographs, giving specimens of fancy turning by an American amateur. The figures were cut on the lathe by a deli-

* "Specimens of Fancy Turning." By an Amateur. Philadelphia: Henry Carey Baird, 406, Walnut-street. London: E. and F. N. Spon, 48, Charing Cross. 1869.

cate pointed tool, kept in position by guides, and pressed at the back by a fine spiral spring. The tool is arranged so that it can be drawn back at any moment by the turner. The interesting process by which the amateur in question—who simply affixes the initials "E. J. W." to a brief introduction—is exceedingly simple. A highly enamelled card is covered with Indian ink, which is laid on by a camel's hair brush. The card is then fastened to the face of a chuck, and the spring tool allowed to cut through the blackened surface of the card, exposing to view the white under-surface of the card. Care is necessary, in selecting the Indian ink, to secure a pure black. Two or three coats laid lengthwise and then crosswise on the card ensures a deep smooth black ground. The author of the elegant examples before us states that his object is only to show the powers of the lathe, and to stimulate others to carry on more completely and systematically similar illustrations, commencing with circles, and advancing with the eccentric, oval, geometric, straight line, and rose engine chucks, both simple and combined. The collection of examples under notice is well worthy the attention of everyone who posesses a lathe.

The long-felt want of a comprehensive collection of illustrations and descriptions of mechanical movements has been supplied by Mr. H. T. Brown, the editor of the "American Artizan." In a very compact form, and in a handy sized volume, we have over five hundred mechanical movements,* embracing all those which are most important in dynamics, hydraulics, hydrostatics, pneumatics, steam engines, mill gearing, and machinery in general. The collection includes many movements never before published, and several which have only recently come into use. The arrangement of the work greatly facilitates reference, the movements being placed on one page, whilst a brief description of them is given on the other. There is also an index which completes the utility of the volume, which will be found very useful by artisans, inventors, and students of mechanics.

Seeing that legislation has of late had a very practical bearing on the working classes, and seeing also that it is likely to affect them still more directly during the next session, Mr. James Samuelson, who is editor of the "Quarterly Journal of Science," and President of the Liverpool Operative Trades Hall, has presented working men with a graphic and instructive picture of one of their order abroad. In the little work before us† the author describes the German working man, his institutions for self-culture, and his unions for material progress. The object Mr. Samuelson had in view in visiting the institutions he describes was to afford our own operatives such information concerning them as appeared likely to be of service in the establishment of trade institutions of an improved kind in England. It is to be anticipated that the proposed special legislation for Trades' Unions will raise the self-respect of our artisans, and will induce them to make greater efforts to cultivate and refine their moral and intellectual character and pursuits. Mr. Samuelson includes in his book a notice of the amusements of working men, which are matters of collateral interest, and of equal importance. The examples given of the means of self-help, education, and art-culture are interesting and instructive, and we trust that every intelligent working man who is interested in promoting the moral and intellectual welfare of his fellows will carefully read Mr. Samuelson's book, for from it he will gather how much can be done by the working classes, by themselves for themselves, if they will only set about it in real earnest. It is not to be done if there is only a half-heartedness, still less can anything be effected if petty jealousies and envyings are allowed to creep in, neither must everyone be a manager. We know of a society of working men which was started about a year since for self-improvement, and in which we took an interest. Books and funds were solicited from outside, and were given; but the whole arrangement and management were undertaken by working men. All went on very smoothly at first, but by degrees it became evident that there were too many masters, and in a few months the society collapsed. Those who read Mr. Samuelson's book will see how this might have been avoided and good results have ensued.

"The Timber Trades' Price Book" is the name of a useful pocket volume of tables and prices, by Mr. W. Richardson, and which has just been published by Messrs. Longmans and Co. We have from time to time had to notice several useful works of a like character by the same author. In the present instance the author gives a set of eight tables and a brief description of each. This absence of all elaborate explanation adds to the usefulness of the book to those who require to make frequent reference to it; and for such it is intended. The practical character and usefulness of Mr. Richardson's previous works is a guarantee of the thoroughly reliable nature of the present production, which we commend to all engaged in the timber trade.

The first to hand of our usual series of annuals is "Pettitt's Annual Diary for 1870,"‡ which comes before us with considerable alterations from previous years, which will be found improvements by its subscribers, who, indeed, must be numerous to enable the publishers to offer such a well-equipped pocket companion for one shilling. This is the twentieth year of its issue, and its success has warranted the enlargement of the almanack, the addition of the mean temperature of every day in the year, together with meteorological and astronomical notes of the month. The daily temperature and the notes furnish the only reliable guide to the weather that science can afford. It is a good sign to see that absurd attempts at weather predictions are being gradually ignored by respectable publishers. We may further state that fresh information has also been added, which will be found useful for reference, and an enlarged monthly form for cash account will be found very serviceable.

The fourth volume of Cassell's technical series has just been published by Messrs. Cassell, Petter, and Galpin, of La Belle Sauvage - yard, Ludgate - hill. It is on systematic drawing and shading, and, like the rest of the series, is progressive and practical. It is by Mr. Charles Ryan, master of the Leamington School of Art, and it embodies a deal of useful information upon the subject of drawing and the materials required. It is illustrated by a number of diagrams, and, with the others of the series, should find a place wherever technical education is being promoted. Messrs. Cassell and Co. have also published a little treatise on vegetable physiology, which was written by Dr. Lankester as part of a series of lessons for reading in schools. The subject is treated in a series of easy lessons, from which we learn the organic, inorganic, and metallic elements of plants, their components, their functions, their germination and nutrition, and their reproduction and decay. It is a useful little book, which will suggest the proper method of studying the great facts of vegetable physiology. "Cassell's Household Guide" is one of the latest productions of this enterprising firm. The first part is before us, and well deserves the attention of every family. It supplies in a plain practical manner all the varied information required in a household, whether large or small, and will amply repay the small amount it costs. Besides woodcuts, it is illustrated by admirably executed chromo-lithographs.

TELEGRAPHIC NOTES.

THE project for a German-American Telegraph cable appears to have been brought to a successful issue. The arrangement, as it at present stands, is that the concession from the North German Confederation of all telegrams for America, not otherwise expressly directed by the sender to be sent by some other route, as well as the right to carry German and English messages, will be effected by a German-English Company shortly to be formed. The concession has been purchased for this new company. The caution money (100,000 thalers) has been deposited, and the necessary contracts and arrangements are being made. A three-wire cable is to be laid from North Germany to Lowestoft, two conductors to be used for German-English messages, and the third exclusively for German-American messages. This third wire is to be connected with one of the Anglo-American wires from Telegraph-street to the United States, which is agreed to be appropriated, but not exclusively, for the transmission of German-American correspondence. The messages will be sent in the order of reception at the terminal and intermediate stations, as required by the International Telegraph Convention. The Anglo-American and Newfoundland Companies are to give a rebate to the German Company on messages passing through the new cable and the Atlantic lines, but the chief source of revenue of the new company is expected to be the German-English traffic, which has increased enormously of late years. The Act of Parliament passed last session specially excepted from the Postmaster-General's monopoly telegrams to and from foreign countries.

We understand that an exclusive concession has been granted by the Spanish Government to Messrs. Graham and Hean, of London, for forty years for a submarine cable from Manilla to Hong Kong and Singapore, and for a telegraph system for the whole of the interior of the island of Luzon; also for all the communications from the island of Luzon to the whole of the other Spanish possessions in thePhilippine Islands.

The whole of the speech of the Emperor of the French was transmitted from Paris to the offices of the Submarine Telegraph, in Threadneedle-street, in fourteen minutes. Five wires were used. We may add that the translation was unusually good, and it was most accurately transmitted.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

TO COLOUR MICA—BLACK FOR PORCELAIN PAINTERS—SOLUTIONS RAISED TO HIGH TEMPERATURES BY STEAM AT 212DEG.—RED DYE FOR WOOL.

WE have more than once noticed the spectacles made of mica intended to protect the eyes of workmen from fragments of metal or stone, and also those of furnace workers from the effects of heat. In the case of these latter, objections have been raised to the whiteness of the mica, and it became desirable to give the spectacles a bluish colour. This was at first accomplished by sticking very thin coloured gelatine on them, but a better plan has been suggested by Dr. Schwarz. What is known by painters on porcelain as "copper lustre" is an organic compound of bismuth with a small amount of gold. When this is put on porcelain and burnt in with a gentle heat it gives a copper-red lustrous mirror. The same solution painted very thin and equally on the mica, and then dried, may be burnt in by the heat of a spirit lamp, and will show by reflected light the same copper-red colour; but by transmitted light, as when the spectacles are worn, the colour seen is a bright blue, which does not at all interfere with vision. Platinum and gold glaze applied in the same way, and burnt in, exhibit a silvery or golden lustre by

reflected light, but by transmitted show grey or greenish blue colour. Dr. Schwarz points out that these effects may lend themselves to a variety of ornamental and decorative purposes.

In connection with porcelain painting we may notice the mention by Böttger of the use of iridium and rhodium compounds for producing an intense black upon porcelain. The material commonly used, which he tells us is a mixture of oxide of iron and oxide of copper, gives very unsatisfactory results. Iridium has now been in use in the royal porcelain works at Berlin for some time. The cost of the new colour will be very considerable, but a little of it will go a long way.

In a paper communicated to the "Chemical News," Mr. Peter Spence mentions the interesting fact that saline solutions can be raised to a high temperature by the use of steam at 212deg. Fah. only. A solution of nitrate of soda, which has a boiling point of 250deg. Fah., was placed in a jacketed pan, and steam was let into the intervening space until the solution was raised to nearly 212deg. The steam was then shut off, and an open pipe was immersed in the solution, and steam thrown directly into the liquor. In a short time the liquor was found to have reached the temperature of 250deg. Fah. The discovery was of immense practical value to Mr. Spence, and will be to every manufacturer who has to boil down large quantities of saline solutions or to digest materials with high boiling points for a long time, since it shows that a naked fire may be entirely dispensed with. It appears from the author's observations that the temperatures to which the solutions can be raised are in the exact ratio of their specific gravities, and have no connection with the temperature of the steam, which never exceeds 212deg. Fah. The greater the specific gravity the higher the boiling point, and whatever the boiling point of the solution, to that point, or very nearly, will steam of 212deg. raise it.

A good and bright red colour, we read, may be obtained on wool by the use of lac dye in the following way. In the first place, a tolerably stiff paste is made of the lac dye and sulphuric acid, and this is allowed to stand for a day. For dyeing ten pounds of wool one pound of tartar, two-thirds of a pound of salts of tin, and three-quarters of a pound of the paste just mentioned are required. The wool must be boiled in the bath for three-quarters of an hour, after which, as a matter of course, it must be carefully rinsed and dried.

SHIPPING IN 1868.

THE vessels built in the United Kingdom, and first registered in 1868, were 1,019 with an aggregate tonnage of 316,197 tons, including seven vessels of 2,005 tons, transferred to the British Possessions. 635, of 88,285 tons, were built of timber; 350, of 206,840 tons, of iron; 34, of 21,072 tons, composite. 102 vessels, with an aggregate tonnage of 46,131 tons, were built in the United Kingdom for foreigners, and not registered in the United Kingdom; of war vessels, two sailing vessels of 1,117 tons, and nine steam vessels of 9,137 tons; and of mercantile vessels, 24 sailing vessels of 7,554 tons, and 67 steam vessels of 28,323 tons. The registered vessels belonging to the United Kingdom at the end of the year 1868 were 24,701 sailing vessels of 4,798,178 tons, and 2,934 steam vessels of 900,596 tons, making a total of 27,635 vessels of 5,698,774 tons, with crews (exclusive of masters) estimated at 248,995. This is after deducting vessels wrecked or broken up. Compared with the return for the end of the year 1867 it shows a decrease of 283 in the number of vessels, but an increase of 28,424 tons. There were also at the end of 1868 809 registered vessels of 81,756 tons belonging to the Channel Islands, and 11,897 registered vessels of 1,456,386 tons belonging to British Possessions, making a total of 40,341 vessels of 7,236,916 tons, manned by crews estimated at 340,516 in number.

BREECHLOADERS.

THE following list of the various breech-loading systems which have been adopted by the armies of the European states appears in the "Eastern Budget":—England—For the conversion of old rifles, the Snider; for new rifles, the Martini-Henry. France—For the conversion of some old percussion muskets, the Snider; for the new rifles, the Chassepot; a metal cartridge is now being made for the latter weapon, the old paper cartridge not being considered satisfactory. Russia—The Kruka for conversions, the 50,000 rifles already converted according to the Karte system having proved failures; Russia has also ordered 30,000 Berdan rifles from America, some of which have already arrived. Sweden and Denmark—The Remington, with Austrian barrels. Norway—Not settled. Italy—Pettiti; similar to the Chassepot (for conversions only). Switzerland—For conversions, the Millbank-Amsler; for new rifles, the Vetterli; Switzerland also possesses 10,000 Peabody rifles. Turkey—The Snider, for conversions. Belgium—The Albini. Spain—The Remington. North-German Bund—The needle gun. Bavaria—For conversions, the Lindner-Podelwils; for new rifles, the Werder. Holland—The Snider, for conversions. Montenegro has obtained 2,000 Kruka rifles from Russia. Austria—For conversions, the Wanzl; for new rifles, the Wernal. Papal States—The Chassepot. Roumania—The Peabody.

THE HEIGHT OF THE BAROMETER IN RELATION TO THE DIRECTION AND FORCE OF THE WIND AT LONDON.*

By MR. RICHARD STRACHAN, F.M.S.

IF it be admitted that every wind has its weather, then a foreknowledge of the weather may be considered possible when the wind can be foretold, whether for brief or advanced periods of futurity. As regards the wind itself there are two things to take into account, the direction whence it comes and the force with which it blows. An inquiry might be instituted as to the indications of the wind's future proximate changes afforded by its veering and alteration of force during assumed intervals of time immediately preceding. In other words, the records of anemometers might be discussed with a view of deducing rules for foretelling wind-changes. Moreover, as the temperature of the air is an element of weather, the records of the thermometer might be consulted to ascertain whether it affords any indications, and under what circumstances, of the coming wind. Further, as the barometer shows that the weight or pressure of the air is subject to ceaseless fluctuation, inquiry may be made whether it can indicate the proximate changes of wind. The barometer has, indeed, been the recognised exponent of weather-changes almost ever since its first invention, and numerous and various are the rules empirically put forth for the interpretation of its action and readings. It must be clear to anyone who thinks about it that such rules can only be legitimately framed from careful investigations of records of barometrical observations conjoined with simultaneous observations of the wind's direction and force, or careful notation of the actual weather-conditions. This, no doubt, has been done to a great extent; but that it has not been overdone will, I imagine, be admitted by most meteorologists. In this manner it occurred to me that an investigation into the relation of barometrical pressure to the direction and force of wind would not be a work of supererogation, and might be attended with some interesting results. Accordingly, I have collated the meteorological observations made by myself, in London, on a systematic plan, from November, 1860, to the end of April, 1869. The 9 A.M. observations being continuous were all used; and to them were added those taken at other hours when the force of wind was what is termed a gale or storm, because there was a deficiency of observations for strong winds, which these additions even have not made numerous enough.

It may be well to state at the outset that all the barometrical observations had been reduced to 32deg. Fah. and the sea-level, that the direction of the wind was always carefully taken by true and not compass bearings, and that grades of force were noted according to Admiral Sir F. Beaufort's scale, 0 to 12. I have not been in the habit of making special records of storms, and, consequently, I have very few entries of forces 10, 11, and 12. What I have have been lumped together under 10.

In the first place the barometrical observations were grouped according to the months, for each grade of wind force, and under each of the sixteen principal points of the horizon in which they occurred. From these groupings it was manifest that, with the same estimated force and direction of wind, the atmospheric pressure may at times be an inch and upwards higher than at others, irrespective of any particular direction or any particular force. Thus, with light winds, with which the barometer usually reads high, the following very low pressures occurred:—

Months.	Force 1.		Force 2.		Force 3.		Force 4.		Force 5.

Lowest of all	28·80	W.S.W.	28·90	W.S.W.	28·78	S.W.	29·02	W.	29·10	E.N.E.

In this table, except N.W., all the directions of wind are represented. Winds with westing are represented 33 times; winds with easting, 19 times. Considering the winds with southing and northing, the numbers are 29 and 11 respectively. Hence light and moderate winds with southing and westing are more frequently accompanied with low pressures than any other direction of winds having similar force, and they are also subject to the lowest of all pressures.

Strong winds are, on the whole, usually attended by lower pressures than light winds; nevertheless the groupings revealed instances of high pressure under every direction of such winds, and showed differences of pressure for winds of the same direction and force equally as great as those exhibited for the light winds. Thus, with strong winds, the following high pressures occurred:—

Months.	Force 6.		Force 7.		Force 8.		Force 9.		Force 10.

* Proceedings of the Meteorological Society.

In this table, winds from S. to S.E. are not represented at all. Winds with westing occur 32 times; with easting, 12 times; with southing, 19 times; and with northing, 6 times. Hence it seems that strong winds with southing and westing are more frequently accompanied by high pressure than similar winds from other directions; but we must also recollect that the wind blows most frequently from between S. and W. The highest pressures, in this class, are apparently due to easterly winds. It is also noticeable that, with the strongest winds (force 8 and upwards), instances of the pressure amounting to 30in. are certainly rare.

The next step was to take the averages of the monthly groups. These averages did not appear to afford any indication of a law connecting the atmospheric pressure with the various directions of winds having the same grade of force, probably because the observations, so numerously classed or subdivided, were in each case too few for the purpose. When, however, the total observations of pressure for each grade of force of wind were meaned according to direction, annual or general averages resulted which appear worthy of some consideration. They are given in the following table:—

OBSERVATIONS OF WIND REFERRED TO SIXTEEN POINTS.

Force 0-12; O. = number of observations; P. = pressure.

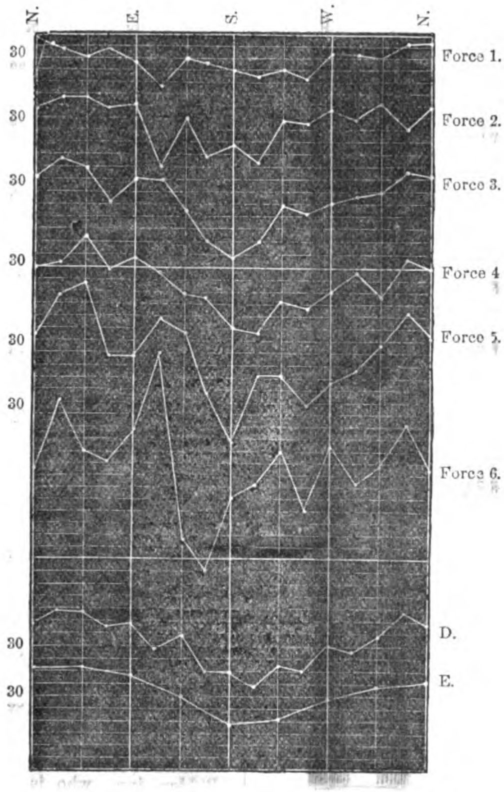
The averages, shown graphically, approximate to curves, having their maxima about N.N.E. or N.E., and their minima at S. and S.S.W. Much of the irregularity of the tracings upon the accompanying diagram may be attributed to paucity of observations under certain directions of wind. The flattest curve appears to be with force 1, and the curvature seems to increase with the force. This tells us that there is more motion in the barometer with equatorial than with polar winds, for a given increase of force. The curve (D) of pressure for direction of wind, irrespective of force, is very similar to the others, and comes out more symmetrically when the observations are referred to eight points only of the compass (curve E).

The whole of the observations of the barometer were next grouped for each grade of the wind's force without regard to direction, with the following results, against which are placed similar results obtained by an investigator unknown to me, who worked up the observations made by Mr. Rogerson, at Greenwich, in 1835-36, and published a short paper on the subject in the "Nautical Magazine" for 1853.

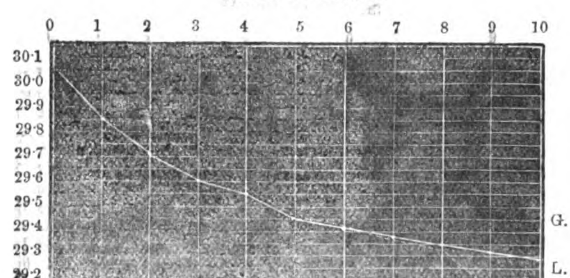
Force.	Years 1860-69.		Years 1835-36.	
	Pressure.	Observations.	Pressure.	Observations.
0.	30·06	90	......	...
1.	30·03	659	30·19	102
2.	30·01	848	30·03	255
3.	29·97	591	29·98	355
4.	29·93	434	29·92	196
5.	29·90	186	29·87	247
6.	29·79	163	29·77	139
7.	29·74	91	29·67	82
8.	29·63	45	29·54	45
9.	29·49	30	29·49	14
10.	29·28	10	29·48	19

These two sets of results are shown graphically in the diagram, marked L and G respectively. They are in close accord with each other, and show a striking decrease in the average atmospheric pressure with the increase of the wind's force.

The average height of the barometer at London is 29·957 inches, from 3,147 observations, the total number employed in this investigation. The resultant of all the observations of the wind's directions, irrespective of force, has been calculated, and found to be W. ½ S.

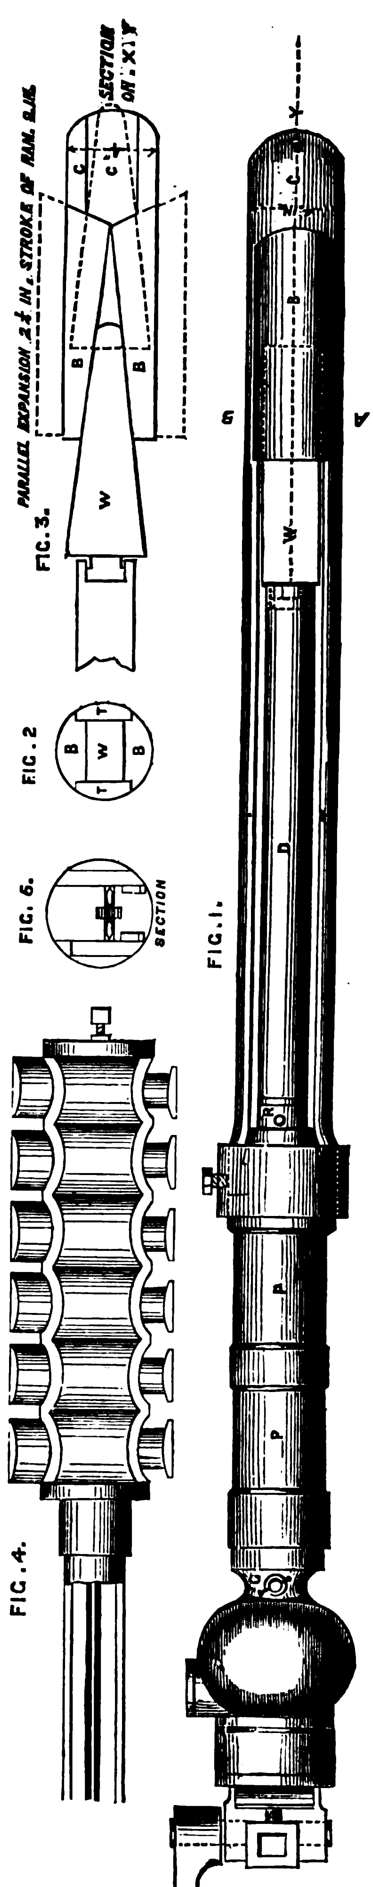


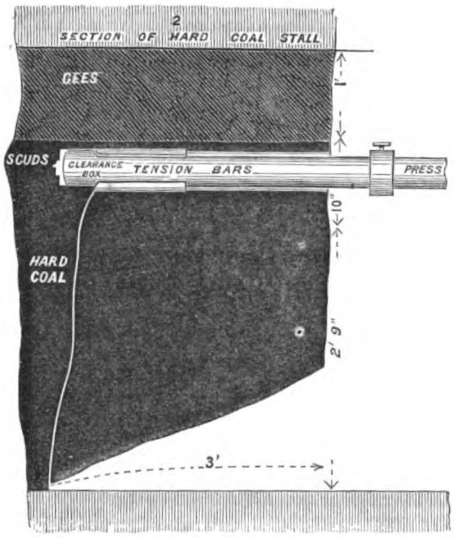
GRADE OF FORCE.

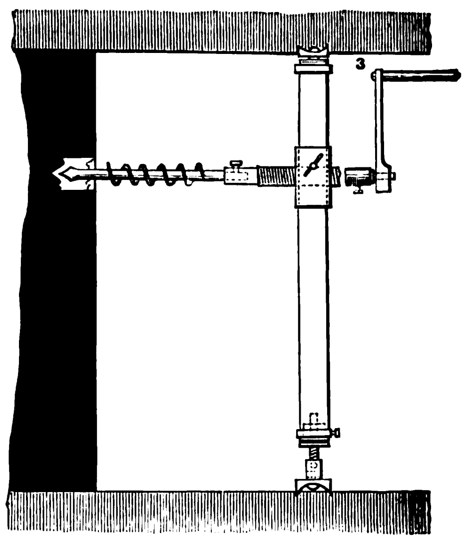


HYDRAULIC COAL-GETTING MACHINERY.

BY MR. J. GRAFTON JONES.







HYDRAULIC COAL-GETTING MACHINERY.

THE feeling that blasting with gunpowder in collieries should be prohibited by legislative enactment continually gains ground with the public, and the success which has attended the practical trials with the wedging machines at the Harecastle and Shipley Collieries is gradually convincing even men accustomed to colliery working that the idea of substituting mechanical for explosive action in the breaking down of coal is not so completely Utopian as was at first supposed. A most interesting paper on the use of hydraulic machines for breaking down coal was read at a recent meeting of the Midland Institute of Mining Engineers, by Mr. Lupton, and we are now enabled to give diagrams of Mr. James Grafton Jones's machine. To facilitate description of these machines, and enable their contemplated sphere of action to be more readily undeistood, Mr. Lupton briefly mentions the principal methods in which coal is got from the solid. According to the first method, the face of the coal is undercut, and the coal either falls by its own weight, or is forced down by the weight of the superincumbent strata. The second method is when the holing is made above the coal, or when the coal is undercut, and will not fall without the application of power. In this case the coal is often blown down by the use of gunpowder, and in other cases where the use of powder injures the coal, or is dangerous by reason of the probable presence of fire-damp, the coal is brought down, or forced up, as the case may be, by means of wedges, driven in by hand hammers. The third method is practised in South Wales, North Staffordshire, and other places where the coal is divided by numerous slines or slips into irregularly shaped masses. At these slines the coal can be so easily separated from the solid that holing is sometimes altogether unnecessary, and here the coal can be got by judiciously placed shots, and by the use of the crowbar and hand-driven wedges. The fourth method is in driving headings, where it is common to hole at the end, and to cut one side, and then to break down the coal by means of gunpowder. In the last three cases it is proposed to supplant to some extent the use of powder and hand hammer-driven wedges by the use of hydraulic machinery. There are three patentees of this description of coal-breaking machinery—Mr. James Grafton Jones, Mr. Charles John Chubb, and Mr. Samuel Parker Bidder, jun., who is associated with Mr. John Jones. Mr. Grafton Jones's patent is dated June, 1867; Mr. Chubb's, May, 1868; and Mr. Bidder's, November, 1868.

The principle of the machine illustrated in the accompanying engravings, for which we are indebted to the "Mining Journal," and which is one of those referred to in the patent of Mr. J. Grafton Jones, of June, 1867, consists in driving a wedge by means of a hydraulic press between two blocks of steel, which are rendered incapable of any but lateral movement by means of tension bars connecting them with the press. In fig. 1, P is the press; R, the ram; TT, the tension bars; BB, pressing block; W, wedge; C, the clearance box, in one piece with the tension bars. The diameter of the clearance box is 4in., and the length of the tension bars and clearance box 3ft. 6in. D is a movable distance piece. The capabilities of the machine were carefully and thoroughly tested by Mr. Lupton, at the Shipley Colliery, in Derbyshire. The Hard coal is there worked on the long wall system, in banks of from 80yds. to 100yds. in length, and the section is—roof bind; Gees, or inferior stone Cannel (used for packs), 1ft.; Scuds (soft coal, 4in.; smut parting, 0; soft coal, 6in.), 10in.; hard coal, 2ft. 9in.=4ft. 7in. The subjoined diagrams show section of a stall on the left side of the gate-road, where a length of 20yds. was holed 3ft. under. At a point, 15yds from the gate end, a hole was drilled in the Scuds, 3ft. long and 4½in. in diameter. The tension bars, with the pressing blocks and wedge, and with the press attached, were then inserted into the hole; the sprags having been removed, the pump was worked by one man, the pump handle projecting sufficiently far from the coal to enable him to work with safety. A few minutes' pumping forced in the wedge between the pressing blocks sufficiently to make the coals bump and crack ominously, and before the ram had reached the end of its stroke the coal was broken down for a length of 10yds., the Gees and Scuds above the parting remaining up. Another hole was then drilled in the Scuds at the point B, in the middle of the length of nine yards remaining between this fall and the gate end. The machine was set to work as before, and this time the length of nine yards was forced down, bringing with it the Scuds and Gees. The remaining part of the bank, 18yds. in length, was then holed, and the machine applied as before, in a hole drilled at the point C in the Scuds. The whole length was brought down at once, the Gees and Scud above the parting remaining up. These experiments being made with the aid of men who had never handled such machines before, and with a drilling apparatus not suited to the position in which the holes had to be drilled, occupied a long time; but it is Mr. Lupton's opinion that two men, accustomed to the work, and with the improved drilling apparatus since constructed, could have easily performed all the operations required in drilling one hole and fixing the machine in 45 minutes, thus taking from two to three hours, and obtaining three falls. The usual time that it would take two men to wedge down as much coal as was done by the machine in these three experiments is between one and a half and two days.

The Shipley Soft coal is worked on the end, and is holed from 3ft. to 4ft. under; it requires to be blown down with gunpowder, and this operation makes a good deal of slack, and fills the air with fumes, objectionable both on the score of health and comfort. Five experiments were made in some Soft coal stalls; the holes were bored 3ft. in, near the roof, and the machines applied as before. The first time, owing to a fault in the coal, a lump of only one ton was broken down. The second time a length of 33ft. of face, and weighing about from 12 to 15 tons, was brought down; the other times, lumps of coal of from 2 to 4 or 5 tons were brought down. In considering the value of these experiments, it must be remembered that the machines were applied without that judgment that experience alone can give, and which would enable much more surprising results to be obtained. In the same stall where these experiments were tried, Mr. Lupton saw two shots fired, each time bringing down a small quantity of coal, not exceeding 1 ton or 30 cwts.

Having brought the experiments at Shipley to a satisfactory conclusion, the invitation of Mr. P. Cooper was taken advantage of to make further experiments at the Holmes Colliery. The first experiment was similar to those already described: a hole was drilled near the roof of a stall in which the coal was holed for a few yards, and one minute's gentle pumping sufficed to fetch down about 5 yards of face. Experiments were then made to see if the

coal could be got without previously holing it; these experiments cannot be said to have as yet resulted in entire success, although enough was done to encourage the writer to continue his experiments in the endeavour to accomplish that most desirable object.

In addition to the wedge-machine, one of another design was used in the foregoing experiments, and proved equally effective. This machine is shown in figs. 4 and 5. It is constructed from a solid round bar of steel, 4½in. diameter and 7½in. long; six holes, 2⅜in. diameter, are bored transversely through this bar. These holes serve for cylinders for as many rams on each side; a hole, ⅛in. diameter, bored longitudinally through the bar, connects these cylinders. To a projection at one end of the bar is screwed a tube 2¼in. external diameter and 17in. long, on to the end of which is fixed a force-pump, made by Tangye. The water from the pump is carried through a copper tube with a very small bore, which is inside the 2¼in. tube above mentioned, and is screwed into the bar carrying the rams; the 2¼in. tube, together with the cast-iron globe to which the pump is fixed, serve as an air-tight reservoir for the water required by the pumps. By working the pump, the rams on either side are gradually forced out from the bar; the rams on one side have a stroke of only ⅛in., and are prevented from coming out of the bar by collars strong enough to stand the pressure. The rams on the opposite side have a stroke of 1⅝in., and the cylinders of these rams have an escape hole for the water, so as to avoid all danger of forcing the rams out of them. It will be seen that by this system of having rams on both sides of the bar no strain is thrown on it. Before this plan was invented rams were placed on one side of the bar only; the bar had thus to sustain the pressure of the rams, wherever, owing to unevenness of the hole, the bar was not supported by the coal, and as a result it was often strained or broken. The spindle that carries the pump-handle, and the short lever (1in. long) that works the pump-plunger, is placed in brackets which can revolve, so that the man who works the pump can have the handle in any position that he chooses. One man can apply a pressure equal to about 10 tons on the square inch by means of this pump. The area of each ram is 4·4 square inches, thus each has a force equal to 44 tons, and all six have a combined force equal to 264 tons.

The area of the ram in the wedge machine is very nearly 6 square inches, and, with a pressure of 10 tons on the inch, it has a force of 60 tons. The stroke is 9in., and the expansion (with the present construction of wedge) 2¼in., thus the power of the ram is multiplied by 4, giving a total bursting force of 240 tons. When the rams in either machines have completed their stroke, by turning the cock C, communication is opened between the pressure-pipe and the air-tight reservoir; the vacuum in this then sucks back the rams, enabling the instruments to be easily withdrawn.

Mr. Grafton Jones has also constructed a modification of the machine last described, the advantage of which consists in doing away with the force-pumps, which sometimes get out of order, and in their place is substituted a screw-ram, which advances into the reservoir of water, and so forces out the short rams on the bar. It is intended also to apply this modification to the wedge machine.

In considering the relative merits of the hydraulic machines, it is impossible to say which is the best, because each one may be found to be the best adapted for one mine, and the worst for another. Where a large amount of expansion is requisite, and only a moderate pressure necessary, the wedge machine will, perhaps, be found the most suitable; but where only a small amount of expansion is required (in some cases less than 1in. is sufficient), and at the same time a very great pressure is necessary, as in the case of breaking down coals that have been undercut, Mr. Lupton thinks the ram machine is the best, because there is less friction in moving the rams than in moving the wedge, and the machine being all in one piece is more handy, and less liable to damage. The application of the screw-pump will be a great improvement. It may also be a good plan to make the rams at the end of the instrument of larger diameter than those near the front of the hole, as more power and a shorter stroke is required at the back of the hole. To conclude, in every case where he has seen the machines tried, they have effectually done at least as much work as powder would have done under similar circumstances, and owing to the gradual manner in which the power is applied, more coal is generally got than could have been done with powder; and although it is not claimed that an acre of coal can be worked more cheaply with these machines than with powder, there is no doubt that less slack is made, and that the condition of the mine is more healthy; whilst where the coal is got by the ordinary plan of wedging, it is the opinion of the writer that a great saving of labour may be in many cases effected by the use of these machines.

MESSRS. J. REID and Co., of Port Glasgow, have contracted to build three steamers of large tonnage for the East India trade, *via* the Suez Canal.

PREHISTORIC MAN.

A SOMEWHAT remarkable discovery of human and animal remains has been communicated by Professor Capellini, of Bologna, to the "Gazzetta dell' Emilia." The Professor, on his return from Denmark, whither he had gone to be present at the International Prehistoric Congress, was rendered so zealous by what he had heard there that he was induced to make many excursions in the neighbourhood of Spezzia. In the course of these excursions he visited many caverns, and in one of these he was successful in discovering traces of prehistoric man. This was in a grotto in the island of Palmeria, the access to which was difficult and dangerous. Here he caused excavations to be made, and the result was the discovery of numerous flint and stone implements, the workmanship of which showed they belonged to the earliest period of the stone age. Besides these wrought implements and various other objects brought into the cavern by its human occupants, he found a considerable quantity of bones of animals mingled with bones of human beings. The condition of these latter bones, he says, "would justify the inference that the grotto had been inhabited by anthropophagi, and that the Italians of that epoch were cannibals, like their contemporaries in Belgium, France, and Denmark. Among the human bones I found those of women, and part of the jawbone of a child some seven or eight years of age. Some of these bones were entire, others were partially calcined. In the centre of the cave it was possible to discern traces of a fire-place. Whoever has busied himself in prehistoric researches, whoever has read Spring's excellent work on the Chauvaux cavern in Belgium, and the writings of other authors on the subject of the caverns in France, will not hesitate to admit that the discoveries in the island of Palmeria prove that the Italians were, as I have said, man-eaters. For the present, it will be sufficient for me to direct the attention of naturalists to the subject. The Cyclopeans spoken of in the fable were probably these cannibals."

GUNNERY EXPERIMENTS AT SHOEBURYNESS.

SIX rounds from the Vavasseur 7in. steel gun were fired yesterday week at Shoeburyness, to try a new modification of the coned-head gear of the screw shaft compressor for checking recoil. In former trials the coned head of the shaft was packed with wood and worked in a wrought-iron female cone; but, in the present case, the coned head was packed with strips of copper about 3in. wide, and worked in a cast-iron female cone, the alteration having been made in consequence of a suggestion that metal working in metal might be preferable for the naval service. The six rounds were barely sufficient to determine the final value of this method of obtaining the second frictional surface for the gearing, but they went far enough to show that the copper might, by wearing surface the porous cast iron, and thus diminish the adhesion or friction, as did, indeed, result in the last round of the practice to the extent of lengthening the recoil by some inches. Mr. Vavasseur contemplates applying a clutch, so as to ensure by mechanical means the absolute cohesion of the two cones. At the previous trial at Shoebury the times of flight but not the ranges with this gun were obtained. On this occasion the ranges were got; but owing to the fog, the times of flight could not be observed. The ranges and accuracy of shooting—which compare exactly with the 7in. 6½-ton service muzzle-loading Woolwich gun, the rifling being the same in twist—were very good, being equal, or, possibly, a trifle in excess of the service ranges. The average of the service 7in. gun at 6deg. 58min. is, with 22lb. of powder and 115lb. projectiles, 3,400yds., as reduced to the plane of the range. The mean of the three Vavasseur ranges is 3,487yds. at 7deg. of elevation with the same charge of powder; but a small deduction has to be made for the height of the position of the gun—namely, 16ft. above the plane of the range. The amount of deflection was only 5yds. in a flight of two miles. The following are the details as given in the "Standard," the elevation being 7deg. throughout:—

Round.	Charge.	Shot.	Compressor at	Recoil. ft.in.	Range. Yards.	Deflection. Right Yards.
1.	... 14lb.	108lb.	... 3¼	... 0·7	... 3232	... 11·4
2.	... 14lb.	114¾lb.	... 2½	... 2·7	... 3103	... 13·6
3.	... 14lb.	114¾lb.	... 2¾	... 2·6½	... 3063	... 15·6
4.	... 22lb.	114¾lb.	... 2½	... 3·7	... 3497	... 15·0
5.	... 22lb.	114¾lb.	... 2¼	... 3·1	... 3475	... 20·0
6.	... 22lb.	114¾lb.	... 2¼	... 4·2	... 3490	... 20·2

Slight differences in the last three recoils were produced by the yielding of the holding chains and pivot of the slide, the soft earth of the marsh never affording a firm bed. A total of more than a hundred rounds have now been fired, and the gun-carriage and compressor remain in excellent order, without showing the slightest sign of wear.

WHITWORTH EXHIBITIONS.

THE £25 exhibitions which Sir Joseph Whitworth offered last year, previous to the competition for the £100 scholarships, proved so successful in bringing together a number of students who, by the aid of the exhibition, had been able to devote a considerable time to their preparation for the examination for the scholarships, that Sir Joseph has this year offered 60 £25 exhibitions, in preparation for the 1871 competition. We see by the "Society of Arts Journal" that these exhibitions have only just been awarded as follows:—

Awarded on the results of the competition for Scholarships, 1869	10

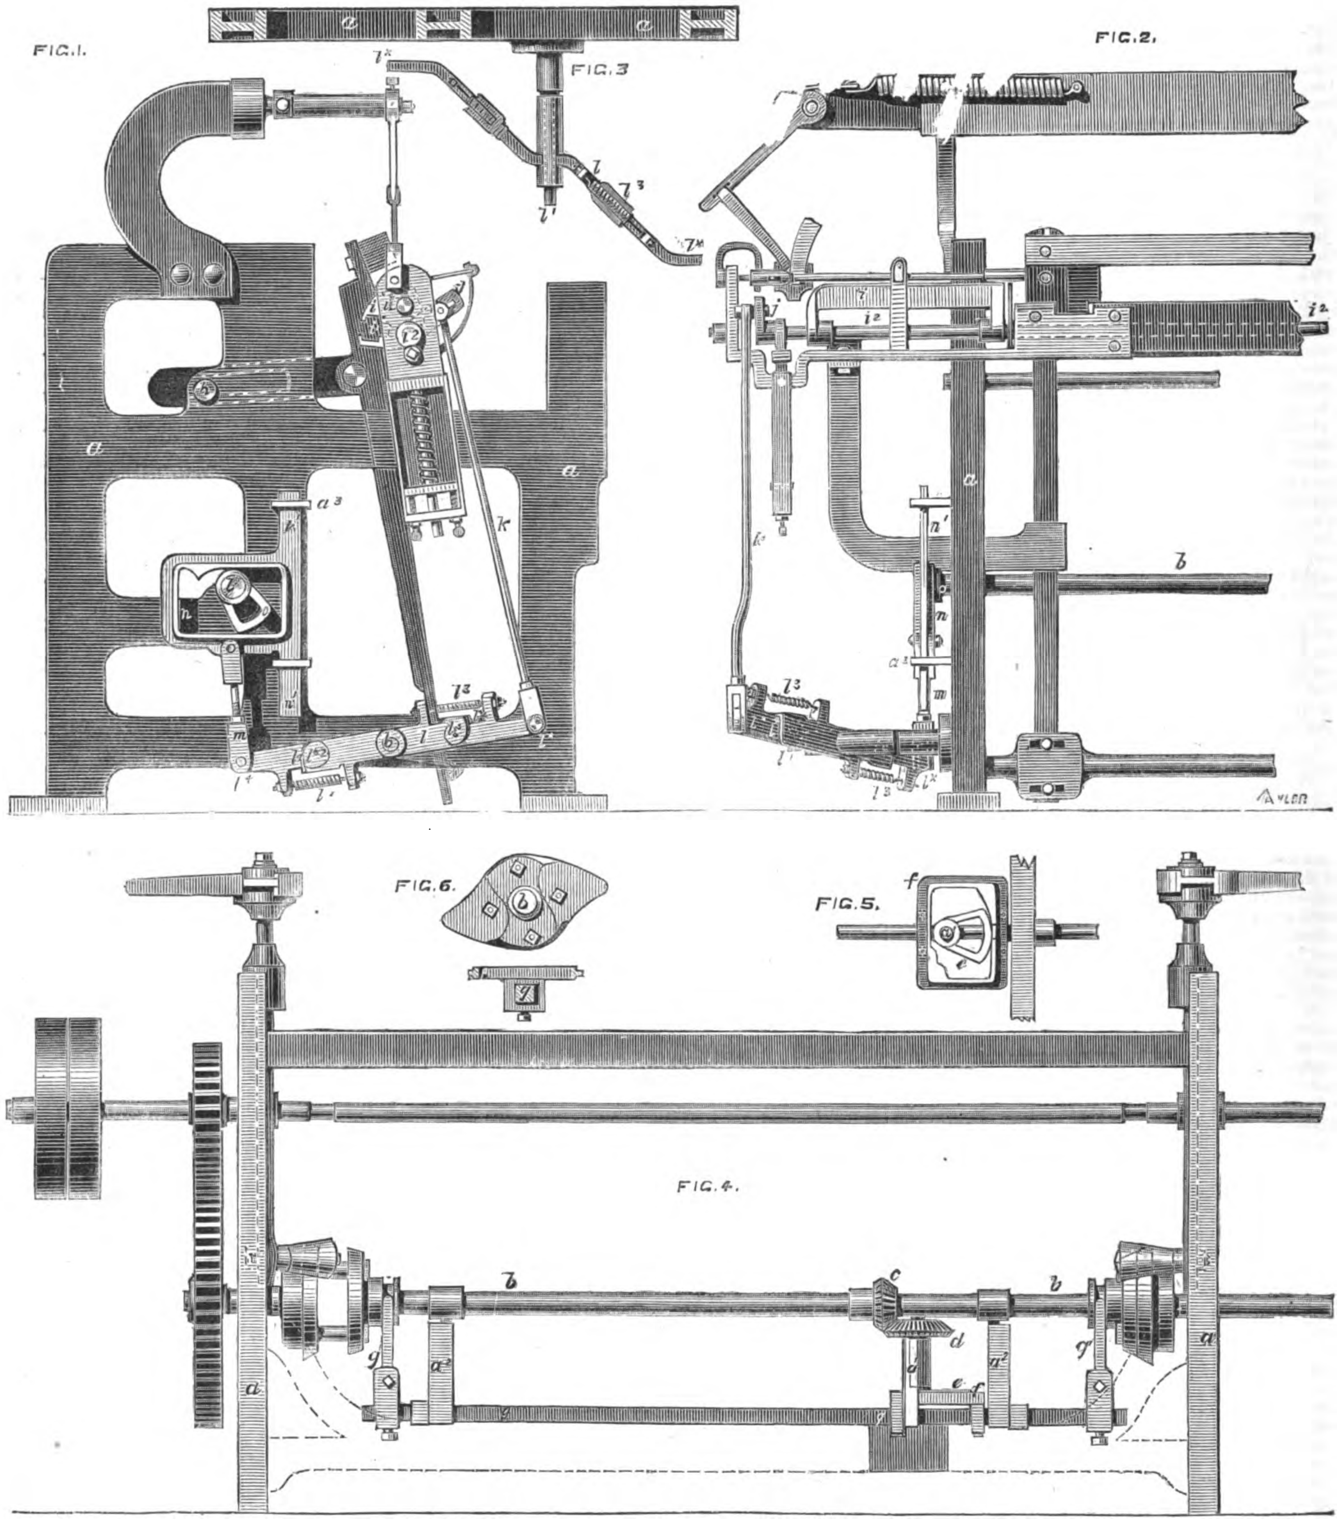
It is to be hoped that the competition of 1871 will be as well attended as this year's was.

IMPROVEMENTS IN LOOMS FOR WEAVING.

MR. GEORGE HODGSON, of Thornton-road, Bradford, Yorkshire, in conjunction with Mr. H. Bottomley and Mr E. Cockroft, has patented a combination of means for effecting variations in the order of selection of shuttles in looms for weaving. The boxes at each end of the batten are affixed to a common axis, which is supported to rock in bearings carried by the batten or going parts, and has applied to it an arm, which by connecting rod and pin joints is attached to one end of an elastic ended lever, the other end of which is by connecting rod and pin joints connected to a frame or fork applied to a rocking arm or lever with means of adjustment as to position for variations of distance of motion obtained. This frame or fork receives and is actuated by a cam or tappet on the tappet shaft

IMPROVED LOOM FOR WEAVING.

BY MESSRS. HODGSON, BOTTOMLEY, AND



Each arm of the elastic ended lever is formed in two parts hinged together, with the part of one arm or one end of the lever capable of turning on its hinge joint in the opposite direction to that of the other. Each arm or end of this lever is held from turning on its hinge joint with a certain degree of rigidity against a stop to each part by springs, yet so as to yield in the event of the shuttle sticking part in the box and part in the shed, or of other stoppage. Upon the tappet shaft is a small bevel tooth wheel of (say) 30 teeth, to gear into another of (say) 60 teeth, upon another axis upon which is also applied a tappet to work in a square casting or frame, or between arms. The square casting or frame is applied on a square rod, which is capable of endway motion, and which carries forks to move the arms of the picker shafts into or out of the way of the picking tappets according to the order of picking for the time desired.

In our engraving fig. 1 shows a portion of the end view of a loom; fig. 2, a portion of one end of the front of a loom; and fig. 3, a plan view of parts separately to illustrate one portion of the invention. *a a* indicates the framing of the loom; *h*, the main or crank shaft; and *b*, the cam or tappet shaft; *i* shows one of the vibratory shuttle boxes, each of which is formed with two shuttle chambers i^1 i^1, and both boxes *i* are affixed to a common axis i^2, so as to be capable of rocking with that axis. The axis i^2 is supported for this purpose in bearings carried by the batten, and it has applied to it the arm *j*, the outer end of which is, by a connecting rod *k*, connected to one end of the lever *l*, which is supported to turn upon a fixed stud or projection l^1, and at its other end is connected by the connecting rod *m* and pin joints to the frame *n*. This frame *n* is formed with arms n^1 n^1, which are capable of sliding in the stationary guides a^3 a^3, as motion is given to the frame *n* by the rotation within it of the cam or tappet *o* on the cam or tappet shaft *b*. It will be seen that each arm of the lever *l* is formed elastic by being formed in two parts capable of turning each in one direction, but each in the opposite direction to that of the other on pins l^2. The parts l^x of each end of the lever *l* are held to act with a certain degree of rigidity by means of the springs l^3 drawing them against the parts l^4, yet so as to admit of their yielding in the event of the shuttle sticking. By the use of cards or pattern surface for actuating the tappet increased variation in the weaving may be effected.

Fig. 4 shows by a back view of some of the

parts of a loom another portion of the invention applied; fig. 5 shows a plan view, and fig. 6 a sectional view of some of these parts of the apparatus separately. *a a* indicates the framing; *b*, the tappet shaft, upon which is applied the small bevelled toothed wheel *c* of (say) 30 teeth, which gear into the teeth of the bevelled tooth wheel *d* of (say) 60 teeth. This wheel *d* is affixed upon one end of a short shaft d^1, which is supported so as to be capable of freely revolving in a bearing provided for it in the cross framing a^1. At the lower end of this shaft d^1 is affixed the tappet *e* in position as it revolves to actuate the frame *f* affixed to the rod *g*, which is supported in a pair of castings, arms, or guides a^2 a^2, so as to be capable of endway motion therein. This rod *g* carries forks g^1 g^1, which embrace the necks of the respective tappets to move them out of the way of the picking cones.

The want of such a loom as we have described has long been greatly felt in the worsted trade, and we congratulate Mr. Hodgson and his co-inventors upon having supplied the deficiency. The loom is at work weaving reps or pick and pick goods. It is very simple and easy of management both for weavers and overlookers. Indeed, there is no more difficulty in the management of this loom than in an ordinary circular box-loom, when the weaver becomes accustomed to it, which he does very quickly. The simplicity of its motions we have no doubt will cause it to come into general use.

MANUFACTURE OF GAS ON A SMALL SCALE.

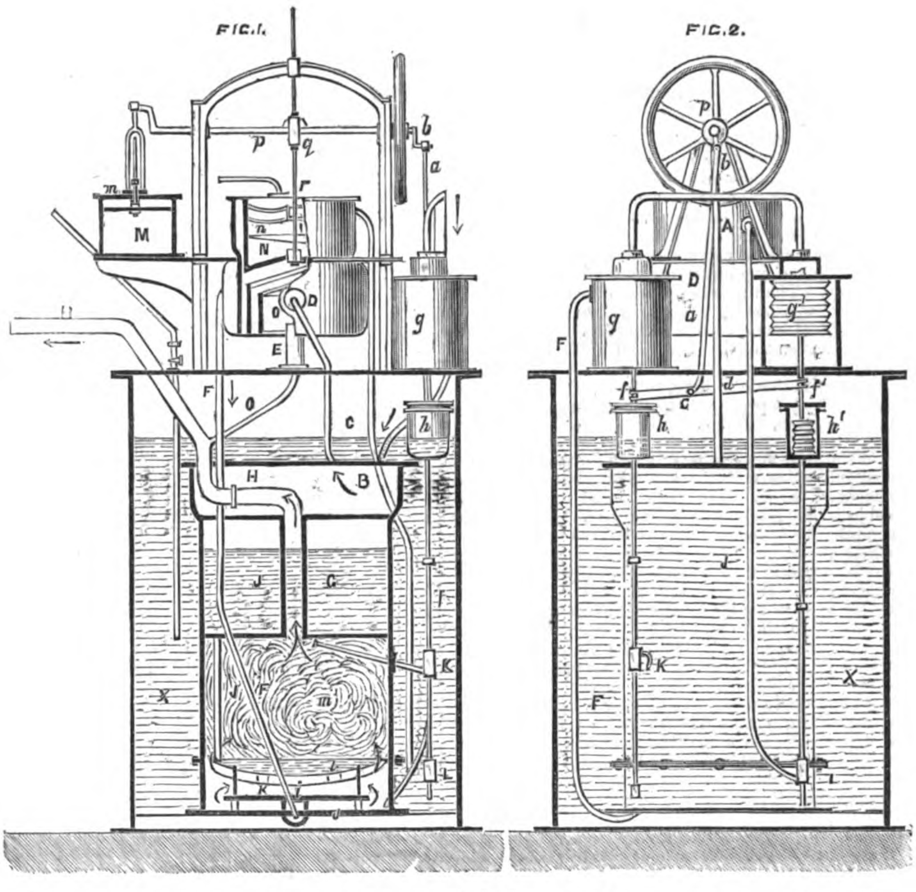
THERE are unquestionably many localities, isolated districts, and detached buildings of various descriptions which it would not be feasible to light by gas by the ordinary process of manufacture. The demand would be too small to warrant the large expense that must of necessity be incurred. To meet the requirements of such cases portable gas-making machines have been constructed, which can be erected at a small outlay, and answer their purposes very successfully. The majority of these make the gas from coal, which, in some instances, forbids their being adopted. A French engineer, M. Lafrogne, has recently patented a small gas-making machine, founded upon the principle of the carburetting of the atmospheric air,* and possessing the following prominent features:—The apparatus is connected with a prime mover, which derives its motive power from a small portion of the gas itself, while, at the same time, it feeds the recipient or vessel in which is placed the carburetting element, which is generally one of the hydrocarburets. A system of valves is arranged by which the air is drawn in, heated in an annular space provided for it, and subsequently transferred to a reservoir, where it is stored under a pressure nearly constant. It becomes saturated with the carburetted vapours by traversing a series of layers of flannel, sawdust, and iron filings, which, by capillary attraction, imbibe and become impregnated with the hydrocarburet, which is thrown upon them by a small pneumatic injector worked by the motive power. After being thoroughly saturated with the carburetted gas the air passes away through an outflow pipe, ready for the purposes of illumination. This small machine is represented in figs. 1 and 2. Fig. 1 is a vertical section, and fig. 2 a side elevation. The motive power consists of a cylinder M, furnished with a piston *m*, and a cold air chamber *n*. This last contains a hollow piston N, or movable box, which is also surrounded with a cold air receptacle. The movements of these two pistons N and *m* are so arranged that when the expanded air has raised the piston *m*, the other rises rapidly to draw in the warm air in the cold part of the vessel *n*, which assists the down stroke of *m*. In the lower portion of the chamber *n* is placed a furnace O furnished with a chimney *o*, heated by the cock E fastened on the tube O, a branch of the outlet pipe H. The piston rod of the cylinder M is connected by a small crank (see fig. 1) to the shaft *p*, and governs the movements of the rod *r* of the hollow piston or box in the chamber *n*. It is this rod *r* that works the valves already alluded to as the means whereby the air is drawn into the apparatus.

Referring to fig. 2, it will be seen that the prime mover imparts motion to the rod *a* through the crank *b*, and that this motion causes the balance

* We extract the cut and particulars from our valuable contemporary "Le Genie Industriel."

APPARATUS FOR THE MANUFACTURE OF GAS.

BY M. LAFROGNE.



rod *c* to oscillate about its centre *d*. This oscillation, in its turn, produces the alternate ascent and descent of the two piston rods *f* and f^1, and thereby causes the corresponding opening and shutting of the four valves *g* g^1, and *h* h^1. Of these the first two are valves of aspiration, and send the air into the body of the apparatus. The duty of the other two will be pointed out presently. After the air has passed by the tube A into the upper part B of the apparatus, which, in fact, constitutes the regulating reservoir, it escapes by the pipe C, and fills the whole of the annular space D which surrounds the burner E. The object of causing the air to enter this space is that it becomes heated, and is thus rendered in a better condition for subsequently becoming carburetted. It escapes from the annular space by the tube F, by which it is conveyed into the carburetting chamber. The tube F is double. In the inner one is carried on the circulation of the hot air, and the space between them is packed with sawdust or other non-conducting substance, so that the air may not be cooled in passing from the annular chamber D to the carburetting receptacle. On leaving the tube F the air traverses the small flannel caps, and then circulates among the plates *j* *k* and *l*, in the direction shown by the arrows. These plates are so arranged as to divide or break the current of air, and thus compel it to become saturated with the hydrocarburet. Above the top plate *l* is the space m^1 filled with wool and sawdust, which are impregnated with that substance. Through this space the non-carburetted air passes by the tube G into the pipe H, whence it is distributed for the purposes of consumption. The hydrocarburet occupies the reservoir J and flows through the pipe J^1 to saturate the absorbing mass m^1, and moisten the plates j^1 *k* and *l*. In addition to this supply the small pump *k* furnishes an extra quantity when required by the small valve *h* has not yet been defined, is that h^1. It serves alluded to previously. The other valve, whose duty to draw cold water into the lower part of the external case *x* by means of the pump L. When it is required to work the apparatus, the first step is to fill the reservoir J with the hydrocarburet selected, and give the wheel a few turns with the hand. In a very short time gas is generated, the burner E is lighted, and the machine continues self-acting. The use of this apparatus is not confined solely to illuminating purposes, but it is equally well adapted for those of heating. In the latter case a worm is introduced into the apparatus through which the air circulates.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

(*Concluded from page 393.*)

THE old antagonism of defence and attack still goes on, but rapid as is the progress in both destruction, if for a short space outstripped by its competitor, is soon far ahead again. With great toil we succeed in opposing a more effective resistance to a force which as surely baffles our efforts. We have reached solid iron plates of 10in. in thickness, but a stronger material is only wanted to give a greatly increased power of penetration to our already formidable cannon and projectiles. Sir Joseph Whitworth has been at work on this problem, and by employing great hydraulic power in forcing cast steel while in a half fluid state into strong iron moulds, he anticipates obtaining its solution. The result of these researches is looked forward to with much interest. If perfectly successful what becomes of our vaunted fleet of armour-encased ships? Employ this same wonderful metal for your ships may be the answer, and so the battle goes on. Nor are we at all sure we have got exactly correct notions of what description of ships is best adapted to carry our heavy gun and to enable us to employ their deadliest effect against a foe. Here the turret principle threatens to displace the broadside, and from the accounts of the Channel fleet on the late cruise the performance of the "Monarch" seems to indicate the class of vessel on which our chief reliance must be placed in naval warfare. When the "Captain," now building at Birkenhead, in Messrs. Laird Brothers' yard, for which Captain Cowper Coles is responsible, has been fairly tried, the question of turrets versus broadside vessels in which that gentleman has so indefatigably supported his side for years will be settled. The course the First Lord of the Admiralty has adopted will leave no excuse as to being misled about the character of our fleet of ironclads, and, as far as we can judge from the accounts, the success of by far the greater number was very equivocal indeed. Putting the

"Monarch" out of court, as this vessel is an adaptation of Captain Coles's system, there is little we can call successful with the exception of the "Bellerophon" and "Hercules," while the "Inconstant" has been nearly torn to pieces by her machinery. It is, however, some consolation that we are better off than any of our neighbours, and we have every reason to believe that in the new turret ship "Captain" we have obtained a superior power of destruction, combined with increased powers of resistance, and, as regards the vessel itself, that we have a ship that will stand up tolerably stiff when our broadsides are making what the sailors call heavy weather, and are unable to take any very certain aim at a foe.

In the commercial marine we have gone on building for the last year at a tolerable rate, and our northern yards have reaped the benefit of the enterprise of our merchant shipowners. Both our navies are interested in the successful voyage across the Atlantic of the great Bermuda floating dock. This gigantic structure was safely towed by two of H.M. steamers, and one light frigate acted as convoy all the way. The time chosen was of course when the calmest weather of the year might be looked for. The signal success of the undertaking, from the commencement of the dock itself to its being safely moored at its destination, will afford a precedent for the construction of others, to be employed wherever this method is preferable to the ordinary system of brick or stone.

We still hear of new schemes for improving our communication with the continent, but no advance has been made. The first official report on the subject has lately been published. It has been compiled by Colonel Tyler, who has examined the whole question. The number of passengers between England and France increases annually to a considerable degree. In 1868 nearly 309,500 persons crossed by the various routes in about the following proportions:—By Calais one-half, by Boulogne one-third, and by Dieppe and Havre the remaining sixth. This shows how much the sea passage is dreaded, as we may conclude the bulk of the passers over went to Paris, or farther south, or vice versa, thus necessitating taking the capital en route. It is dislike to the sea alone that has caused so many to avoid the preferable journey by Dieppe. Owing to the want of better harbour accommodation it is found impossible to employ vessels of greater length than from 200ft. to 240ft., or drawing more water than 7ft. or 8ft., and even then vessels cannot at all times enter the French harbours. While condemning the style of vessel employed of necessity at present, Colonel Tyler recommends that a proper pier be constructed at Boulogne, as more suitable than Calais, and this can be effected for £500,000. The accommodation necessary would be secured on the French side by a judicious extension of the west pier at Boulogne, while at Dover for £100,000 the improvements required in the jetties for embarkation and disembarkation could be made. By employing steamers capable of moving in either direction with equal facility, the difficulty of turning in small harbours would be avoided, and the existing harbours of Boulogne and Dover slightly modified would be available for improved steamers. This scheme is proposed for the temporary improvement of a wretchedly uncomfortable service, if the two governments are disinclined to carry out Mr. Fowler's plan of a Channel ferry, which that gentleman estimated at £2,000,000, inclusive of steamers.

In connection with railways the most important and prominent feature of the past year has been the question of the tariff, and a keen controversy, opened up in a great measure by our late president's startling and forcible statement as to non-paying weights, has been maintained on this subject. Its importance is very great, since it involves the whole question of railway management, and raises considerable doubts as to the fitness of the present means to the end. While railway companies cannot be expected to carry goods and passengers at rates which cannot pay interest on the capital sunk in the undertakings, fares injudiciously low adopted to serve a merely temporary purpose accustom the public to this tariff. When the existing cause, be it a "beggar my neighbour" rivalry, or a bait to lure the public to settle in greater or less numbers at a little distance from large towns, is removed, and the more legitimate equilibrium restored, this same public considers itself ill-used. The gist of the whole matter lies in the fact that in many cases the difference between receipt and expenditure leaves no margin in many cases for a return on the capital invested. No doubt much money has been spent foolishly in the construction of many unnecessary and mischievous branch lines, and even when such were advisable much of the expense incurred might have been avoided by the adoption of a road more in proportion to the traffic it was designed to accommodate. Rivalry culminating in the heavy expense of competing schemes, and the enormous expenditure known as parliamentary expenses, have thrown a heavy burden on the backs of railway companies, which the travelling public must ultimately support. Thus immense capital invested, heavy working expenses, and above all many branch establishments which continually and heavily drag on the parent house, together with dissatisfied customers, form the chief difficulties directors have to encounter. How can greater receipts be obtained? Offer your goods at much lower figures, and an immense increase of custom will fill your empty coffers, say some quidnuncs. But it has been demonstrated by statistics and the inexorable logic of figures that this nostrum is utterly valueless. Many of our lines are encumbered with their traffic, and the anticipated increase necessary to make a lower tariff even equally remunerative with what now obtains could it be realised would be extremely difficult to deal with. It is not possible that a train can always be equally filled with passengers, for many circumstances combine to carry crowds in certain directions at certain hours and seasons when no impelling cause supplies anything like a similar number for the return journey. Traffic managers know very well the statistics of the travelling public, and do their best to provide for all possible contingencies. It may be said that trains are run too frequently, and it may be so, but this does not strike at the root of the matter. Railway companies must be possessed of a rolling stock adequate to the demands of their heaviest traffic, nor would some less costly means of obtaining the necessary powers of construction, though most desirable, tend one whit to improve the position of companies already existing. The question is unalterable—on one side a certain amount of capital and certain working expenses, on the other a certain income. That this latter is lamentably deficient with many of our companies is painfully apparent from the reports of the directors. To improve matters it is recommended that the expenses of management, assumed to be extravagant, be reduced, but I contend that on the whole railway officials are not overpaid, and whatever cheese-paring might be effected in this direction could at most amount to a mere "drop in the bucket." Whatever improvements of a radical nature may be adopted must be made in the mechanical appliances for working the traffic of our iron roads and Mr. Fairlie's arrangements of the bogie truck system applied throughout to carriages, waggons, and locomotives point to the commencement of a new era for railway companies. With our present system Mr. Haughton has shown that a railway passenger weighs in reality two tons the moment he enters the carriage of a train, while Mr. Samuels confirms the estimate of Mr. Fairlie, who puts the figure a little higher, in fact, two and a quarter tons. The latter gentleman, however, does not stop here, but has demonstrated that it is possible to carry 66 persons in a steam carriage, at a weight of eighteen and a half tons, all told, and has exhibited a little train of this description at actual work. In a cabbage garden at Hitcham this steam carriage has been whisked along at good speed round very exceptional curves of 50ft. radius. Mr. Fairlie, now assisted by Mr. Samuel, has also designed another carriage with engine attached which will weigh along with its living freight of 90 passengers only 20 tons. In these cases in place of 132 or 148 tons, we have 18½, and for 180 or 202 only 20 tons. The temporary rails on which the first-mentioned of these trains has been run experimentally are by no means smoothly laid, but even on this rough road the motion of the carriage even when rounding exceptional curves is easier than that of an ordinary train on a well-laid road. Again, with regard to goods traffic Mr. Fairlie has built a locomotive capable of hauling 800 tons. While the weights of this engine are better distributed over the wheels, they are not in the aggregate heavier than those of heavy locomotives of the ordinary type, and nearly double work is performed One of this new construction, fitly named "Progress," has been at work for some months past on the Midland Railway with the most satisfactory results. At a public trial it dragged a train of from 60 to 70 coal waggons, weghing 700 tons, up a rising gradient of 1 in 108, and of more than a mile in length, at a speed of 15 miles an hour. Nor is this the most powerful Mr. Fairlie can construct, and yet it greatly exceeds in power the heaviest in ordinary use. Now here we have the proved success of a new description of rolling stock, capable of performing every species of service required on a railway at an immense reduction of weight. It may be objected that a steam carriage is not adapted to the service of a main line. But the principle is clearly susceptible of much modification and adaptation, and so far as the engine itself is concerned, we have the precedent of the goods locomotive on the Midland Railway, nor do the advantages end with the mere weight to be transported. The wear and tear of engines, carriages, and waggons, and of the permanent way itself, are chiefly owing to the severe concussions which result from every roughness and inequality in the road. Everyone is tolerably conversant with the uncomfortable shocks which frequently occur even in the course of a short journey by train, and most of us have observed how hard the flanges of the wheels of carriages bear on the rails when passing round a curve, when the connection also between carriage and carriage is formed by the coupling and one buffer only. The buffers on the outside of the curved train are some little distance apart, and the ordinary amount of unsteadiness is very much increased when passing over any roughness. This is certainly a matter which could be remedied by a reciprocating arrangement between the buffers at each end of each carriage. These things all of us know very well, but only the locomotive superintendent and the custodian of the permanent way are fully cognisant how destructive these shocks and concussions prove to engines, carriages, and waggons, as well as to the road itself. The oscillation, with which too we are very familiar, and which banishes sleep from many on a night journey, is also owing to our present system. This, too, Mr. Fairlie removes, and with such success that the motion of his locomotives is compared to the ease of a bird's flight by Captain Tyler, the government inspector, who travelled on it at the rate of 50 miles an hour, thus bearing witness to the comfort in store for us. It is easily understood that by hanging our engines and carriages on two or more points in the centre line lengthwise, and establishing a connection by a swivelling joint at each of these points, with a bogie of a very small wheel base, we obtain trains capable of moving round very sharp curves. Experiment has established how safe and steady is the motion, which will at once appear infinitely better adapted for the inequalities of even the best roads than the long rigid wheel base we employ at present. The absence from shocks in the ordinary course of traffic resulting from this arrangement might admit of buffers being dispensed with throughout an entire train, with the exception of the end carriage or brake van and the engine. For this object Mr. Fairlie recommends that the end beams of carriages be formed as arcs of circles struck from the centre of each carriage, to which point he would attach the draw bar; when a train is made up, each carriage would be coupled up closely to its neighbour, and thus under all conditions one point only, but always one point, of each carriage would be in close contact with its fellow, and the whole train would preserve more or less a constant and flexible continuity. So far as goods trains are concerned, dead weight of freight must of course remain a constant, but even here there would be a gain as compared with our present system in the relative lightness of the new style of locomotive and waggons.

That great desideratum, then, smoothness of motion, and consequently the longer life of rails and rolling stock, combined with much greater economy of working, are certain results which will follow the adoption of Mr. Fairlie's arrangements. The development of the bogie truck system points clearly in the direction of a more remunerative return on the immense capital invested in railways, and even at the possibility of lower fares. The dividends of the last year are on an average nearly the same as those of the preceding, and the number of companies whose unfortunate ordinary shareholders receive nothing at all bears a painfully large proportion to those paying from 5 per cent. upwards. It is of the utmost importance that some better method of working our railway traffic be adopted, and any scheme devised for this end is worthy of all encouragement, and Mr. Fairlie has proved by actual practical demonstration that his system of arrangement is perfectly safe, and that it contains the elements of a wide success. This year has been rendered famous in engineering annals by the completion of three great works, two of which are of international or rather universal interest. The great continent of North America is crossed from ocean to ocean by the Pacific Railway, an undertaking of the first magnitude. A third link, in the shape of the Anglo-French Telegraph Cable, forms with its two elder brothers a triple bond between the old world and the new, symbolical, we all trust, of a clearer recognition of how closely our interests and those of our transatlantic cousins are united. It will indeed be an evil day should our good relations be disturbed, equally disastrous on one side as on the other. The Suez Canal forms the last, not in magnitude but in point of time, and it is confidently anticipated that this great water highway will be magnificently inaugurated, and Africa reduced from its ancient dignity of a continent by being formally declared an island. Invitations for the grand ceremonial have been issued with no sparing hand, and I have the pleasure of informing you that our society has not been overlooked. But the gathering to witness the successful results of M. de Lesseps' many years of labour, put at the disposal of all who may choose to make use of his canal, will be, indeed, a wonderful spectacle. All civilised nations will send their contingents to applaud the great enterprise of the Frenchman, who has made the desert to blossom, and has added another to the number of the great works of a world fame which have so eloquent a blazon in the aphorism "Peace hath her victories as well as war." To the effects of every one to these bloodless conquests may well be applied the motto once appended to the admission cards of an art exhibition, for these victories are triumphs of art of the highest order, with its attendant handmaids, Labour, Patience, and Skill. Of each of these gigantic undertakings it may well be proclaimed "Dissociata locis, concordi pace ligavit."

THE LEEDS ASSOCIATION OF FOREMEN ENGINEERS.

THE fourth anniversary festival of this institution took place on Saturday, the 27th ult., at the Great Northern Railway Station Hotel, Leeds. Mr. John Manning (Messrs. Manning, Wardle, and Co.) presided, and was supported by Mr. Wigram, Mr. Greig, Mr. Walker, and several more of the employers of engineering labour in the town of Leeds. The assembly room of the hotel was filled with members and friends of the society, and Messrs. J. Newton and R. B. Sanderson represented the London and Manchester associations. The Chairman, in proposing the toast of the evening—that of "Prosperity to the Leeds Association of Foremen Engineers"—made the following judicious remarks:—'Mr. Fowler and Mr. Hawkshaw, when successively elected presidents of the Institution of Civil Engineers, both acknowledged how greatly they were indebted for their professional success in life to the efficient staffs by whom they were surrounded. I have endeavoured to show you that the profession of an engineer is a very honourable and important one, and I am proud to think that Leeds stands high as a mechanical town. The cloth trade and the flax trade were for generations counted the staple manufactures, but I think I am not wrong in saying that the iron, engineering, and machine trades now rank first in importance. If this be so, how great the responsibility and opportunities of the positions we occupy as employers and foremen! We, as employers, have opportunities of meeting each other at our own institution; but this is the foremen's night; we have met to do honour to them, and we can well afford to admit the importance of their aid and to acknowledge our obligations to them in matters of detail. Let us not distrust these men and their objects; let us tell them to-night that we believe they meet for mutual improvement and instruction alone; that we regard their association as one means of technical education, of which there is so much need; and that we hope and believe that in the course of time the prejudice of which they complain will gradually die away. You, too, as foremen have your share of responsibility; for what is theory without practice, what a good design carelessly carried out, what machine will work well if its details be imperfect? Let us, then, by all means maintain the highest possible standard of excellence in our work. Let us trust in each other. Let the master believe that if he only have the sagacity to select the right foreman, he may and ought to trust him; and let the foreman feel that by studying his employer's interests he is likely to improve his own position—then shall we go strong-handed together, maintaining our own against all comers, and thus shall we support the credit of our town, the honour of our country, and help to uphold the fame of England as the first mechanical country in the world.

Mr. Harrison, chairman of the association, responded, and when, shortly afterwards, Mr. Gozney gave the toast of "Kindred Institutions," Mr. Newton, who acknowledged it on behalf of the London association, spoke to the following effect:—'It is not my intention to accept as applicable to myself alone the compliments which Mr. Gozney has so unstintingly bestowed. I am quite aware that they are intended for distribution amongst the members of the society which I have the honour to represent—the London Association of Foremen Engineers. It will be a real pleasure to me to convey to them the assurance of your continued and hearty friendship, as it is now my mission to assure you of theirs. We feel a deep interest in the welfare of this association, and of that which flourishes in Manchester, because we know that their members are animated by views and aims identical with our own, and that those views and aims are of the most laudable kind. You, like us, have sought, and are seeking, to elevate the class of foremen engineers especially, and to make them at once better men and more valuable and effective agents of their employers. So far as the London association is concerned, I can answer for the fact that its existence has proved of real advantage to every section of representatives of the engineering trade in the metropolis, and, perhaps, not least to the employers of engineering labour. It has been my own policy, as its chairman, and that of each succeeding committee with whom I have acted, to endeavour as far as in us lay to remove those unhappy prejudices which have existed in time past, and which, to some extent, exist at present between the classes to which I have referred. We have sought to demonstrate the fact that we as foremen desire to have the friendship of employers, both in the workshop and out of it, and to co-operate with them everywhere and at all times for the promotion of the moral and material interests of the combined body. That this policy has been appreciated by employers is evidenced by the circumstance that more than forty of the most eminent of them are honorary members of the London association, and that on all occasions similar to the present they delight in honouring with their presence our festive board. My own impression is that if all employers could be brought to see clearly the exact nature of our associations, they would foster and encourage them in every possible way, and one and all unite themselves to them. We do not, never have, and never shall attempt to make our institutions in any way the medium for interference with what are the just rights and privileges of employers. To do so would be simply attempting to accomplish what in the first place would be an injustice, and in the next a suicidal act. I can well understand employers unacquainted with the internal mechanism of such societies as our own may imagine that it is possible for communications to take place at their meetings of a character inimical to employers' interests. The only way which I can propose for the removal of these not unnatural doubts is that employers should join the association. But I can assure them that after being a member of the London Association of Foremen Engineers for fourteen years, and having occupied the post of chairman of it for ten years, I have never known an instance in which an employer's confidence has been there betrayed or a revelation made to his detriment. In conclusion, permit me again to thank you for your hospitality, and for the enthusiastic manner in which you have received the toast for which I have so inadequately responded. Mr. Newton was followed by Mr. Sunderson, who responded for the Manchester association, and the Rev. J. P. Ward, who represented the Leeds Mechanics' Institution. Other toasts of a complimentary nature succeeded, and when Mr. Manning retired, Mr. Newton was unanimously voted into the chair for the remainder of the evening. The National Anthem terminated the proceedings.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, December 2.)

SINCE our report of the 22nd ult., the business transacted has been sufficiently encouraging to sustain prices and keep producers well engaged. The demand for present consumption is perhaps a little easier, consumers, as usual at this time of the year, regulating their orders to provide for small stocks at Christmas. The chief feature of importance is the probable weakening in the prices of nitrate soda. Our advices from Valparaiso state that the shipments of this year, up to September, are 88,000 tons, being already a considerable increase on the total shipments of either 1867 or 1868. In minerals of most descriptions, but more especially in the staple home productions, there has been a fair business done. The advance in iron has produced considerable firmness in the prices of the oolitic and other ores of the Midland district. There has been little change in the value of metals during the week, and the sales have been inconsiderable, with the exception of Scotch and Cleveland pig iron, in both of which a satisfactory business has been done at advanced prices, the market closing very steady. Copper is not in great requirement, but smelters are firm at present rates. Tin and spelter remain quiet. Lead in good inquiry at full rates. Soda: most of the largest consumers have completed their contracts for twelve months supply. Prices of soda ash, caustic soda, soda crystals, and salt cake remain stationary. Bi-carbonate easier at £9 5s. Nitrate of soda: meets with an ordinary sale at 15s. 6d. to 16s. Potash: muriate is not sufficiently plentiful to keep pace with the consumption, and prices rule from £7 7s. to £7 10s. Saltpetre: a shade lower for foreign, 22s. 3d.; refined firm at 27s. Alum: finds a steady demand at £6 5s. for loose lump; £7 for export barrels; and £7 for ground. Ammonia: sulphate firm at late high prices; muriate, being difficult to obtain, commands a proportionately higher value. Copperas: at old prices, 50s. to 52s. Lime: phosphate remains at 52s. 6d. for 65. Bleaching powder at £8. Manganese: steady at 95s. for 70. Iron ores: hematite, 15s. to 18s.; oolitic in great favour at 6s. to 8s. Staffordshire. Guano: is offered at £13 7s. 6d. to £13 10s. 6d.

METALS.—Iron: Scotch pigs firm at from 56s. 2d. to 56s. 3d. Cleveland, 46s. for forge, and 50s. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire bars, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: firmer. English tough, £71 to £73; Chili slab, £67 to £68. Tin: English is officially reduced. English ingots, £120; Straits, £114 to £115. Lead: steady. P.G. best English soft pig lead, £19. Spelter: in moderate demand. English, £20 10s.; Silesian, special brands, £19 10s. to £19 15s.; hard spelter, for export, £16 10s.

Legal Intelligence.

ROLLS' COURT.

NOVEMBER 25.

CANNINGTON v. NUTTALL.

THIS case was to determine the validity of a patent granted to a M. Pocheron for an invention for improvements in the manufacture of glass, consisting mainly in the substitution for the fire-clay pots usually employed to hold the molten materials of tanks or basins, the sides of which are hollow, so that a current of cooling air may be admitted to circulate and prevent the sides from being unduly heated. This patent was dated May 6, 1866, and was assigned to the plaintiffs, who are glass manufacturers at Liverpool. They allege that the defendant, who is a glass manufacturer at St. Helen's, has erected a tank or furnace, which is an infringement of the patent.

Certain issues have been tried before a jury in the Rolls' Court, and to-day the jury found a verdict for the plaintiff in respect of the originality, novelty, and utility of the invention, and of its infringement by the defendant.

Mr. Fooks, Q.C., Mr. Jessel, Q.C., Mr. Webster, Q.C., Mr. Grove, Q.C., Mr. M'Naghten, Mr. Aston, and Mr. Carpmael appeared.

Correspondence.

COMMITTEE OF THE BRITISH ASSOCIATION ON THE TREATMENT AND UTILISATION OF SEWAGE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I beg to enclose herewith a copy of a circular letter which the above committee are about to issue to all the towns in Great Britain and Ireland, and to request that you will kindly insert the same in your columns.—I am, Sir, yours, &c.,

GEORGE F. BARNES,
Honorary Secretary *pro tem.*

22, Whitehall-place, November 27.

"SIR,—I have the honour to inform you that last year at the meeting of the British Association at Norwich, a committee was appointed to report on the treatment and utilisation of sewage. In the first instance, a grant of £10 was placed at the disposal of the committee, with which to defray the cost of printing and postage incidental to the collection of preliminary statistical information. Through the kindness of her Majesty's Government the committee was enabled to obtain reports respecting the methods of dealing with town refuse practised in most civilised countries, and that information has now been collected in a more complete form than hitherto existed in any country.

"This preliminary work being completed, the committee was reappointed at the meeting of the British Association this year at Exeter, and the inquiry was considered to present such important features of social and scientific interest that the sum of £50 was voted towards enabling the committee to enter more fully and practically upon the investigation of this subject. The British Association being a purely scientific body has not at its disposal funds which would be adequate or applicable for the full prosecution of this very large and pressingly important inquiry. The committee nevertheless desires to take advantage of the opportunity created by the British Association to investigate the entire subject in all its bearings—whether chemical, physiological, or engineering, sanitary, municipal, or agricultural—and in a manner worthy of the body they represent.

"It is unnecessary to point out the enormous importance, especially at the present time, of a full and complete investigation of this question by the light of the knowledge and experience now gained in the several departments above alluded to; but properly to carry out such an inquiry with a practical end numerous observations, gaugings, and experiments, aided by simultaneous analyses, are essential; and these cannot be accomplished, especially the analyses, without the continued aid of efficient, and, therefore, highly-paid assistants. Moreover, from time to time it may be necessary for the committee to purchase expensive apparatus, and to subject various inventions and processes to a thorough and complete test; for it is the desire of the committee not only to ascertain, as far as possible, the causes of the sanitary inefficiency of existing works, but also to inquire into every suggestion which affords promise of practical utility, in order that this investigation may be searching, the report practical, and any recommendations that may be made authoritative.

"It is the wish of the several members of the committee to devote, to the utmost of their ability, their personal attention to the work thus sketched out; but the expenses absolutely necessary to enable them to conduct so extended an inquiry cannot but be very heavy, and, unless they are able to secure an adequate fund, they must aban-

don the attempt to investigate the subject in this broad and comprehensive manner. However, since there is no subject of greater practical and social importance to the public generally, and thus to the various municipal authorities and other governing bodies throughout the country, it is believed that many will share the opinion expressed at the recent meeting of the British Association at Exeter, that the existence of this committee affords a specially favourable opportunity for such a wide inquiry, and for that reason its members confidently appeal to those authorities who are officially interested in the subject to supply the funds necessary for the investigation.

"I am, therefore, desired to request that you will kindly submit this letter to the body you represent, and I venture to hope you will give the committee the benefit of your good offices in procuring a subscription proportionate to the population of your town or district.

"It is suggested that the subscriptions of towns of different populations might be graduated somewhat in the following proportions:—

	£	s.	d.
Where the population does not exceed 10,000	5	5	0
Between 10,000 and 25,000	10	10	0
Between 25,000 and 50,000	21	0	0
Between 50,000 and 75,000	30	0	0
Between 75,000 and 100,000	50	0	0
Above 100,000	100	0	0

"I beg to call your attention to the accompanying list of members of the committee, and to inform you that all public bodies subscribing not less than £5 5s. will have the benefit of the information from time to time, as the results of the inquiry partake of a conclusive character, and will receive a copy of the report of the committee when published.

"I have the honour to be, Sir,
"Your obedient servant,
"GEORGE F. BARNES,
"Honorary Secretary *pro tem.*"

The following are the names of the committee:—Messrs. Richard B. Grantham, M. Inst. C.E., F.G.S., chairman; J. Bailey Denton, M. Inst. C.E., F.G.S.; J. Thornhill Harrison, M. Inst. C.E.; Benjamin H. Paul, Ph. D., F.C.S.; Professor Wanklyn, F.C.S.; Mr. William Hope, V.C.; Professor Williamson, Ph. D., F.R.S.; Professor Marshall, F.R.S., F.R.C.S.; Professor Corfield, M.A., M.D.; Mr. M. C. Cooke, and Sir John Lubbock, Bart., F.R.S., treasurer.

Subscriptions should be paid to the credit of Sir John Lubbock, on behalf of the committee, at Messrs. Robarts, Lubbock, and Co., 15, Lombard-street, London, E.C.

THE CANADIAN PATENT LAW.

Mr. A. V. Newton presents his compliments to the Editor of the MECHANICS' MAGAZINE, and will feel obliged if he will give publicity to the following correspondence, which may be of interest to many of the readers of the magazine.

To the Right Hon. Earl Granville.
Secretary of State for the Colonies.

MY LORD,—I venture, before the new patent law of Canada is confirmed by the Crown, to recall your attention to one of its provisions, which can, I think, scarcely meet the approval of her Majesty's Government. You will remember that during last session this question was asked in the House of Commons, viz., "whether the Colonial Office was prepared to recommend the Government to advise her Majesty to withhold or postpone her assent to the Bill, with a view to give an opportunity to the Canadian Legislature to reconsider its provisions." The reply of Mr. Monsell was variously and evidently very imperfectly rendered by the daily papers, but those points which a concurrence of testimony supported may, I presume, be taken as correctly printed. He is reported by the "Times" to have said that "the subject of patents was essentially one with which the dominion of Canada might deal, and this was evidenced by the terms of the 18th sec. of the Imperial Act 15 and 16 Victoria, cap. 83," and then the clause was quoted. The inference drawn from this quotation was, according to the "Morning Post," that "we really had no more to do with the passing of the patent laws in Canada than we had to do with those of France." The concurrent testimony on this point is thus given by the "Morning Advertiser":—"As to refusing the Royal assent, they were precluded by the terms of a former Act of Parliament from having recourse to such a proceeding." I may here state that the Act of the Imperial Legislature will bear no such construction, for the clause is simply a saving clause, to the effect that if British patents are granted with an extension of the same to the colonies (a practice which formerly obtained) that then, if a local Act comes into collision therewith, the home grant shall have no effect as opposed to the colonial law. By order of the Colonial Office no extension to the colonies has ever been made under the Act of 1852, and, therefore, the clause cited is virtually a dead letter. Referring now to the Act of the dominion of Canada (1869), it will be found, when read by the side of the Acts which it has repeated, to have deprived certain of her Majesty's subjects of rights which they heretofore enjoyed, and on this ground, if upon no other, I submit that it should be disallowed by the Crown. Before the passing of this Act any subject of Great Britain residing in Canada might obtain a patent for his invention. Now, however, a prohibition is created by altering the provision to "a resident of Canada for at least one year next before his application." To say nothing of the policy which a "residence" in Canada points to, I think a great principle is here set at nought, viz., that subjects of the Crown may claim equal rights throughout the empire. I could point to the unjust and oppressive action of this new law, but I refrain, trusting that your Lordship will appreciate the importance of the principle I have enunciated, and will not suffer the maimed rights hitherto possessed by British inventors under the Canadian patent laws to be destroyed.

I am, my Lord,
Your Lordship's obedient servant,
A. V. NEWTON.

November 9.

Downing-street, November 29, 1869.

SIR,—I am directed by Earl Granville to acknowledge the receipt of your letter of the 9th inst., remonstrating against the provisions of the recent Patent Act passed by the Canadian Legislature.

Lord Granville desires me to inform you that your representation will be considered before any advice is tendered to her Majesty on the subject of this Act.

I am, Sir,
Your obedient servant,
FREDERICK ROGERS.

A. V.Newton, Esq.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

MR. JOHN GRAY (Toronto).—We have forwarded your letter as requested, and the firm have acknowledged its receipt.

RECEIVED.—G. W. H.—W. F.—H. J.—R. B.—N. and Co.—L. and P.—H. E. H.—T. C.—E. F. B.—J. G.—H. F. W.—E. M.—J. J.—B. R. and F. T.—J. R.—T. C.—R. W.—S. M.—W. L. W.—D. S. N.—R. S.—T. B. E.—H. W. F.—T. Meetings for the Week.

MON.—Royal Institution.—General Monthly Meeting, at 2 p.m.

TUES.—Institution of Civil Engineers.—Discussion on "The Public Works in the Province of Canterbury, New Zealand," by Mr. Edward Dobson, A.I.C.E.; a paper on "Ocean Steam Navigation, with a view to its further development," by Mr. John Grantham, M. Inst. C.E at 8 p.m.

Naval, Military, and Gunnery Items.

THE standard for recruits for the Royal Marines has been raised half an inch.

THE Secretary of State for War has invited tenders for the purchase of 8,000 Whitworth rifles, now lying at the Tower. The arms are identical with those used in the Second Stage of the Queen's Prize at Wimbledon, and are described as "new and slightly used."

MESSRS. A. and J. INGLIS have launched a screw of 1,500 tons, built for the Shanghai Steam Navigation Company. The vessel, which has been named the "Shan Tung," will be fitted with a pair of direct-acting surface-condensing engines of 160-horse power nominal.

THE Thames Conservators have given notice of their intention of applying to Parliament next session for powers to widen, deepen, and improve the River Thames and its tributaries, to remove bridges, regulate the discharge of sewage, and to levy taxes to carry out these works.

WE understand that it is in contemplation to cut down the staff leave of the army. The fact that staff clerks get 61 days' furlough in the year has attracted attention, and it is under serious consideration to diminish this, and the leave of the department officers as well generally.

SOME experiments which are considered to have been very successful have been made in the Medway, at Gillingham Reach, near Chatham, with a newly-invented torpedo, under the superintendence of the chief officers of the School of Military Engineering at Brompton.

IT is stated that Messrs. Shaw and Thomson, of Leadenhall-street, iron merchants, have undertaken to act as advisers and agents of the Admiralty in the disposal of the large stock of surplus iron stores at the dockyards, in which are embraced the quantities that have obtained notoriety as "Seely's pigs."

THE Viceroy of Egypt has given an order to the Societe des Forges et Chantiers de la Mediterranee for a large floating iron dock. The total length of the dock will be 470ft. 10in., and its internal breadth will be 80ft. The breadth of the sides will be 10ft., so that the total external width of the dock will be 100ft. The height will be 36ft. 8in., and the weight 4,600 tons.

TWO very handsome and capacious steam lifeboat pinnaces, Nos. 18 and 19, built for her Majesty's navy, by Mr. John Samuel White, of East Cowes, Isle of Wight, were recently tried at Portsmouth, under the supervision of the Steam Reserve and factory establishment, with very satisfactory results, both boats attaining a mean speed of upwards of eight knots per hour.

WE, "United Service Gazette," are in a position to state positively that no attempt will be made to disband the military train upon the formation of the new transport corps. The military train will co-exist with the new corps until all the officers and men are provided for. The mess-traps, &c., of the officers will all be duly taken up by the War Office at their estimated value before the final abolition takes place.

THE "King George," Greek ironclad turret ship, which left Plymouth on Tuesday week for the Piræus of Athens, in charge of Commander Pym, R.N., has been compelled to put back to Plymouth Sound, in consequence of her rolling so heavily, even in fair weather, as to be considered unsafe to proceed on the voyage. She is evidently over top-weighted—a defect which will have to be counteracted before going to sea again.

THE "Eddystone," screw, built and engined by Messrs. Blackwood and Gordon, of Port Glasgow, for the Clyde Shipping Company's Glasgow, Cork, and Waterford route, has made a favourable trial trip. The "Eddystone" is a vessel of 700 tons burden; her length is 190ft., her breadth 27ft., and her depth of hold 14ft. 6in. The engines, which are of 100-horse power, are on the compound principle; the high-pressure cylinder is 2ft. 6in. in diameter, and the low-pressure 46in. in diameter.

COLONEL BOXER, R.A., has resigned his appointment of superintendent of the Royal Laboratory, and his resignation has been accepted. Colonel Boxer's successful exertions in connection with the improvement of our war *materiel* are known mainly through the fuses, shrapnel, shell, life-saving rockets, and breech-loading cartridges with which his name is associated; but these are only the more conspicuous examples of an inventive faculty which for fifteen years has been in constant operation for the public benefit.

WITHIN the brief compass of a week, the oldest of famous American sailors and the oldest of famous American soldiers passed away. Rear-Admiral Stewart in his 92nd year, Major-General Wool in his 86th, lay in state together on the 10th ult. The press and public men of the country pronounced upon them simultaneous eulogies. Over their bodies their younger comrades and their countrymen bent at the same moment, while the flag under which they had fought for half a century together, on land and sea, and to which they had given by their skill and valour so lustrous a prestige, ran down to half mast in a common token of national sorrow for a double calamity.

Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending November 27, was 1,103. Total number since the opening of the Museum, free daily (May 12, 1858), 1,683,171.

THE imports of rough iron into the Zollverein in the first half of this year amounted to 74,121 tons, or 22,084 tons, or 42 per cent. more than in the corresponding period of 1868.

THE Liverpool magistrates have decided that a bicycle is a carriage within the meaning of the Act, and have fined a youth for driving one upon a footpath.

VELOCIPEDES are gaining ground in Sydney. They are not so commonly met with as at Melbourne, but races are got up at the Albert Cricket-ground.

AT some granite quarries in the neighbourhood of Camborne, Cornwall, on Saturday, a 9ft. deep hole, charged with 56lb. of powder, was fired, the explosion removing from 700 to 800 tons of granite.

THE death of Mr. John Hodgson Hinde, M.P. for Newcastle from 1830 to 1847, is announced at the age of 64. The deceased was an eminent archæologist and antiquarian, and the author of several standard works.

AT the ordinary meeting of the Manchester Literary and Philosophical Society, held November 16, 1869, Mr. J. P. Joule, LL.D., F.R.S., &c., President, in the chair, Professor Osborne Reynolds, B.A., of Owen's College, was elected an ordinary member of the society.

AT the latter end of last week Italy was visited by very heavy snow-storms. The railway communication across Mount Cenis was completely stopped, and even as late as Friday the snow on the mountain was four feet deep. The obstruction, however, has been removed, and traffic is now carried on as usual.

THE Prussian iron trade displays considerable firmness; some contracts for rails and other materials have recently been let; thus the Nassau and Wiesbaden and the Hanoverian Railway Companies have ordered between them 1,656 tons of cast steel rails, besides a considerable quantity of ordinary iron rails and iron sleepers.

CONTINUED activity still characterises the French iron trade, at any rate, so far as the departments of the Haute-Marne, the east, the north, and the Ardennes are concerned. In the Haute-Marne the water supply has been completely re-established, and rolling mills, forges, wire works, &c., are all well employed.

THE "Moscow Gazette" says that, according to official returns, there have been more fires in the Russian empire this year than were ever known to have occurred before. The total number, so far as is known, exceeds 15,000. The value of the property consumed can only be roughly estimated for about four-fifths of them, but this gives it as exceeding 25 millions of roubles.

THE new session has just commenced at the Ecole des Beaux Arts, Paris, and the following is the list of students in the various sections:—School of painting, seventy pupils, and ten supplementary, or candidates for admission; sculpture and medal engraving, twenty-seven pupils and ten supplementary; architecture, thirty-nine pupils. Total, 156 titulary and supplementary students.

THE Agricultural Society of New South Wales is progressing. Negotiations are being made between the Corporation of Sydney and the society with reference to the erection of a large building in the Alfred Park, to cost £14,000, and in view of the guarantee that will be required for its occupation for a term of years the society is now going into incorporation.

THE number of visitors to the South Kensington Museum during the week ending November 27, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 6,851; Meyrick and other galleries, 849; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,714; Meyrick and other galleries, 73; total 9,487. Average of corresponding week in former years, 8,800. Total from opening of Museum, 8,968,858.

A MELBOURNE paper says that the satisfactory intelligence received by the last few mails, respecting the disappearance of the prejudice once existing against Australian preserved meat as an article of food, has not only led to the formation of several new companies, but has encouraged manufacturers at present in the field to extend their operations. A company re-commenced operations in June last, since when they have shipped 300 tons of meat in tins, and the whole has met with a ready sale.

ADVICES from Buenos Ayres mention that the samples forwarded for competition for the premium of £800 offered by the Argentine Government for the best method of preserving meat in a fresh condition were opened on the 1st of October in presence of the jury. "The smell," it is stated, "was in most cases very offensive, but of the 35 samples there were half a dozen good, and one in particular sent from Glasgow is likely to take the prize." The jury, however, had not yet decided.

THE extent of the railways in operation in France at the close of September, 1869, was 10,302 miles, as compared with 9,929 miles at the close of September, 1868. It follows that the length of new railway brought into operation in France in the 12 months ending September 30 this year was 373 miles. The work of railway construction is probably now proceeding faster in France than in Great Britain, France being still by no means over-supplied with railway communication.

"NATURE" announces that the three annual medals of the Royal Society have been awarded thus:—The Copley medal goes to M. Regnault, one of the first among the many living French physicists and chemists; one of the Royal medals has been conferred on Dr. Matthiessen, distinguished for his chemical and physical researches; while Sir Thomas Macleat, the Cape astronomer, with whose valuable contributions to science all are doubtless familiar, carries off the other. The medals were presented on the 30th ult., at the annual meeting of the society.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1413, 1435, 1456

BUILDINGS AND BUILDING MATERIALS—1404, 1432, 1445, 1455, 1466

CHEMISTRY AND PHOTOGRAPHY—None

CULTIVATION OF THE SOIL, including agricultural implements and machines—1406, 1417, 1422

ELECTRICAL APPARATUS—1441, 1467

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1367, 1410, 1421, 1437, 1462, 1470, 1478

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1414, 1419, 1449, 1450, 1457, 1468

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1407, 1408, 1416, 1423, 1428, 1453, 1474, 1480

GENERAL MACHINERY—1405, 1459, 1465, 1475

LIGHTING, HEATING, AND VENTILATING—None

METALS, including apparatus for their manufacture—1409, 1418, 1426, 1431, 1433, 1434, 1443, 1446, 1452, 1458

MISCELLANEOUS—1401, 1402, 1403, 1420, 1424, 1425, 1429, 1440, 1442, 1457, 1461, 1469, 1471, 1472, 1473, 1476, 1477

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1411, 1415, 1438, 1439, 1447, 1454, 1463

SHIPS AND BOATS, including their fittings—1460, 1464

STEAM ENGINES—1423, 1444

WARFARE—1427, 1430, 1436, 1448, 1479

1367 J. BULLOUGH, Accrington. *Warping machines.* Dated May 4, 1869.

The inventor employs a novel construction of drop pin, in the body of which an enlarged pear-shaped eye with a stem above and a stem below is formed. The lower stem of the improved pin is of the same strength as that now in general use, but the upper stem is considerably lighter and is also bent or cranked near its extremity. The pin from the foot of the upper stem has an open or pear-shaped eye formed in it, which is provided with a side opening or slot, through which the continuous thread is passed into the eye.—Patent completed.

1401 E. SEYD, Princes-street. *Fluid meters.* (A communication.) Dated May 7, 1869.

This consists of a rotary fluid meter with a stationary outer casing and a movable inner casing in combination with one or more pistons, rolling upon the casings or their equivalents with the necessary ports, channels, and appendages.—Patent completed.

1402 R. FENNELLY, Wellington Chambers, E.C. *Washing out casks.* (A communication.) Dated May 7, 1869.

This consists in so constructing the apparatus that the casks to be washed may be carried upon a horizontal revolving table in such manner that they may be caused not only to revolve upon an axis standing up from the table, but also that the cask may at the same time be caused to revolve on its own longitudinal axis. By this means, when the table carrying the casks is caused to revolve, the water previously placed in the casks is thrown away from the central axis of the table, whilst the cask, being at the same time caused to revolve simultaneously on two axes, which are at right angles to one another, every point of the interior of the cask must necessarily be subjected to the action of the water.—Patent completed.

1403 D. and A. POSENER, Mansell-street, Goodmans Fields. *Tobacco pipes.* Dated May 7, 1869.

The inventors place at the bottom of the bowl a plug of peculiar construction, so that the oil or moisture from the burning tobacco may be absorbed or taken up by the porous part of the plug, and thus be prevented from entering the pipe, stem, or tube.—Patent completed.

1404 G. N. MANSFIELD, Great Portland-street. *Parquet flooring.* Dated May 7, 1869.

The inventor uses veneers of hard or ornamented woods (by preference from one-eighth to one-sixth of an inch in thickness) for the wearing surface of the covering, as has heretofore been proposed. These he backs with strips or sheets of the substance known in the market as kamptulicon, rolled to a thickness (say) of about one twelfth of an inch. The veneer he attaches to its backing by means of a solution of glue.—Patent completed.

1405 J. RAMSBOTTOM, Leeds, and T. M. PEARCE, Bradford. *Steam and hydraulic apparatus.* Dated May 7, 1869.

On the cylinder end of a steam or water pressure pumping engine and forming a part of its end cover, the inventors cast a small valve cylinder at right angles to the cylinder proper, and in this valve cylinder they place a piston valve intended to be moved longitudinally in either direction by the steam or water with which the engine is worked.—Patent completed.

1406 A. J. MURRAY, Albany-road, Camberwell. *Reaping and mowing machines.* Dated May 7, 1869.

The inventor takes a tube of the required length and of any convenient diameter, and divides the same longitudinally through its centre or through any desirable part thereof, so as to form an upper and lower part. The lower part is to be fixed to the frame of the machine, and the upper part is to be made movable upon centres or hinges at the back of the tube, or jointed in any other suitable manner. The fingers are divided into two parts; the upper part is to be riveted or otherwise fastened to the upper part of the tubular bar, and the lower part of the fingers is to be riveted or otherwise fastened to the lower part of the finger bar.—Patent completed.

1407 F. LEONARDT and H. HEWITT, Birmingham. *Pens.* Dated May 7, 1869.

This consists in making in the points or nibs of pens a series of transverse corrugations or depressions, or curved or angular corrugations or depressions, for the purpose of forming a reservoir for the ink, and to give the pen an easy action in use. The corrugated nibs or points may either be perforated or unperforated.—Patent completed.

1408 J. G. TONGUE, Southampton-buildings. *Manufacture of envelopes.* (A communication.) Dated May 7, 1869.

A series of swinging shears are so applied as to cut out the envelope blanks one at a time by a series of shearing cuts from one thickness, sheet, or long strip of paper, so that there is little or no waste except at the necessary gores removed at the angles of the envelope to allow the flaps to lap in. Folding shears arranged in this manner cut out one blank envelope at a time, and the cutting edges remain in working order for a considerable time. When dull they can very readily be ground.—Patent completed.

1409 Sir F. C. KNOWLES, Lovell-hill, Berks. *Purifying cast iron.* Dated May 8, 1869.

The main feature is the retention of chemical substances below a bath of molten metal in order to purify and convert the latter. Shotted metal is principally used. Caustic soda mixed with pulverised ore is employed to form a base to take up the acid. The gas to be employed is produced from chalk or limestone mixed with charcoal. A very great heat is caused from this gas, which is passed through the body of the metal. The furnaces are made in a peculiar manner to suit the above processes.—Patent completed.

1410 W. HENDERSON, Glasgow. *Finishing woven fabrics.* Dated May 8, 1869.

The two endless chains ordinarily employed in these machines for holding the selvages of the fabric by means of stenter pins or clips are as usual passed round pitch wheels at each end of the machine and along grooved guides. These guides are formed or fitted along the top and bottom edges of vertical side plates extending horizontally from end to end of the machine and made about as broad vertically as the diameter of the pitch wheels. The fabric is entered at one end of the machine, passes along the top to the other end, and returns along the bottom to within a short distance of the entering end, being thence led away in a downward direction; an enclosed space is thus formed having the fabric for its top and bottom, whilst vertical plates form its sides. Heated air, by means of a pipe, is blown into this space for the purpose of drying the fabric.—Patent completed.

1411 B. HUNT, Serle-street, W.C. *Horse collars.* (A communication.) Dated May 8, 1869.

This consists in dividing the collar into two parts, so arranged as to be extended or contracted at will, in length or breadth, according to the size or conformation of the neck and shoulders of the horse.—Patent abandoned.

1412 H. MYERS, Miles Platting, near Manchester. *Furnaces of locomotives.* Dated May 8, 1869.

This consists in making the doors of locomotives and other furnaces to slide in a vertical direction in place of opening on hinges, or being made in two halves and sliding in a horizontal direction.—Patent abandoned.

1413 E. MAYBURY, G. MATTHEWS, and E. MARSTON, Pendleton. *Puddling furnaces.* Dated May 8, 1869.

The hearth is surrounded or partially surrounded by a hollow metal box or chamber, through which water is caused to circulate in order to keep the box and the fettling in immediate contact therewith comparatively cool.—Patent abandoned.

1414 R. and G. CADBURY, Birmingham and J. M. BENDALL, Torquay. *Cacao biscuit.* Dated May 8, 1869.

The cacao bean is ground in the customary manner, and when ground, there is associated with it farinaceous matter, sugar, and butter. The whole is then mixed and prepared in the usual manner to form the biscuit.—Patent completed.

1415 E. S. COPEMAN, Norwich. *Communicating in trains.* Dated May 8, 1869.

In the roof of each of the compartments of the carriages to which it is desired to apply the apparatus, two

holes or apertures are made. The apparatus consists of a box, the base or bottom of which fits on or covers the before-mentioned holes or apertures, any suitable contrivances being employed for keeping it in a firm position. Each side of the box is constructed with vertical slots, through which the arms used for signalling are capable of passing. One of such arms is placed at each side of the box.—Patent completed.

1416 A. B. HAWES, India Office, Whitehall. *Bottles and flasks.* Dated May 8, 1869.
The cap or stopper has two or more grooves, more or less deviating from a horizontal line formed circumferentially near the neck. Each of the grooves is at its lowest point cut right through to the edge of the cap, forming a notch in the same. In each of the grooves fits a corresponding stud or projection fastened to or in one with the neck of the bottle, each stud and groove together forming a joint somewhat similar to a so-called bayonet joint.—Patent abandoned.

1417 W. N. NICHOLSON, Newark. *Haymaking machines.* Dated May 10, 1869.
This consists in the introduction of carrier pinions, in consequence of which the speed at which the forks revolve may be varied, a circumstance of great practical advantage in haymaking. When it is not required to vary the speed, the carrier pinion may be withdrawn.—Patent completed.

1418 H. R. LUMLEY, Marlborough-place, St. John's-wood. *Purifying molten iron.* Dated May 10, 1869.
Instead of forcing air through the mass of molten iron, the inventor allows it to fall from a sufficient height in the smallest particles, or in a thin shower through an upward rushing blast of heated air.—Patent abandoned.

1419 H. DUFRENE, Paris. *Desiccating and preserving food.* (A communicaton.) Dated May 10, 1869.
The inventor places the substances to be treated in a receiver kept in a hot water bath at a suitable temperature. He forms a vacuum in the receiver. The vapours disengaged from the substance to be desiccated are dissolved by an absorbing agent placed in the apparatus, or are liquefied in a condenser suitably placed. The desiccation is then effected.—Patent abandoned.

1420 E. FIELD, Chandos Chambers, Adelphi. *Steam fire engines.* Dated May 10, 1869.
This consists in actuating the valves which regulate the admission and emission of steam to and from the main steam cylinders of steam pumping engines by means of tongues or levers actuated by curved or inclined surfaces in or in connection with the main pistons.—Patent abandoned.

1421 C. LAUTH, Paris. *Dyeing and printing.* Dated May 10, 1869.
This consists of improved means whereby both animal and vegetable substances can be died or printed with aniline black. The inventor commences by fining thereupon bioxide of manganese, preferably by means of a permanganate dye, but any process that will thoroughly fix the superior oxides of manganese is applicable to this invention. The fibres thus covered with bioxide of manganese, and generally known as plain goods, are caused to undergo a process of washing for the purpose of separating those parts that do not combine with the fibre, and that would eventually fall away in the dyeing bath, and thus cause considerable loss in alkaloids. The inventor then proceeds with the dyeing process.—Patent completed.

1422 R. BLEZARD, Liverpool. *Dressing millstones.* Dated May 10, 1869.
This consists in giving to the radial arm or arms whereon the tool carrier or tool carriers are made to slide to and fro, either by itself or themselves or with the supporting frame, an intermittent motion over the surface of the millstone, around the centre thereof, or around an eccentric point or points thereon.—Patent completed.

1423 W. CURRIE, Edinburgh. *Cushions.* Dated May 10, 1869.
This consists in substituting for the materials or springs hitherto employed for the purpose hollow airtight pads or balls, which are laid together and enclosed in a covering of cloth, velvet, leather, or other suitable fabric or material.—Patent abandoned.

1424 M. S. WOLFGANG, Stratford-le-Bow. *Cricket balls.* Dated May 10, 1869.
The inventor employs as usual a core of compressed cork, which he binds by means of canvas, cotton, twine, or other suitable material, as heretofore. He then covers the core with indiarubber to obtain the required size and shape, and submits it to the action of heat, until the necessary degree of hardness is obtained, but as the application of heat to the materials composing the ball as before described would tend to injure the core and the binding material, he places between the binding and the core and between the binding and the indiarubber a coating of asbestos.—Patent completed.

1425 R. F. HOPPE, Cheapside. *Musical boxes, albums, &c.* (A communication.) Dated May 10, 1869.
This consists in so adapting musical boxes, albums, and other articles of a similar description, that, in addition to the ordinary mechanism for playing tunes, an arrangement is effected for the display of photographic portraits, views, and other pictures, which are made to revolve underneath the lid or cover of the musical box or album, and be seen through an opening in the same, and so continue to revolve as long as the music is playing.—Patent completed.

1426 W. E. NEWTON, Chancery-lane. *Hardening iron.* (A communication.) Dated May 10, 1869.
In the process of converting iron castings into steel, the inventor uses black oxide of manganese, peroxide of iron, and common resin, or their chemical equivalents, in about the following proportions, viz., 25 parts of manganese, 15 parts of peroxide of iron, and 60 parts (by weight) of common resin.—Patent completed.

1427 W. E. NEWTON, Chancery-lane. *Gun locks.* (A communication.) Dated May 10, 1869.
The inventor provides a movable nipple guard, which will prevent the hammer from falling upon the cap in case of accidentally becoming disengaged from its holder, by any means other than the regular action of the trigger in discharging it. This nipple guard will also by the action of the trigger be moved out of the way of the hammer when regularly discharged.—Patent completed.

1428 W. B. SMITH, Coventry. *Watches and chronometers.* Dated May 10, 1869.
The positions of the pillars which are at a proper distance from the edge of the plates are as follows:—One is on the escapement side of the barrel, having both the top plate and barrel bar screwed to it; one is between the escape wheel and fourth wheel; one is inside the detent spring just at the back of the detent; and one instead of two between the fusee and barrel behind the third minute division. This last pillar in the half-plate movement being higher than the others by the thickness of the top plate, and having the extended barrel bar only screwed to it.—Patent completed.

1429 J. WITHERS, Handsworth. *Water meters.* Dated May 10, 1869.
The inventor fixes to the outer ends of the measuring cylinders a cylindrical valve case, having two lateral openings communicating through the end of the measuring cylinder with the interior thereof. In each of these valve cases work two piston valves so disposed that when one of the openings, say the inlet, is open to the cylinder, the other outlet shall be closed or *vice versa*.—Patent completed.

1430 W. R. LAKE, Southampton-buildings. *Bronze ordnance.* (A communication.) Dated May 10, 1869.
The inventor hardens, condenses, and smooths the metal surrounding the bore, rendering the bore of uniform size, and lessening its inner depressions and porosity. He effects this condensation substantially in the following manner:—If a bronze gun is to be treated, the inventor bores the rough casting carefully to secure the best bore possible to a diameter about ½in. less than it is to be when finished. The rough gun casting is then to be enclosed in such hoops or flask as will constitute a strong casing, but as the exterior of the casting is rough and irregular, as is also the exterior of the casing, the inventor leaves between the gun casting and casing an annular space to be filled with cement or other suitable cheap material, which will make a hard unyielding filling. The encased gun is then to be placed in a frame or upon a bed somewhat like a boring mill for guns, but instead of using a bar provided with cutters, the inventor fixes in the end of the bar a smooth cylindrical plug of hardened steel about 5-100in. larger than the diameter of the reamed hole in the gun. The plug should be made of two frustrums of cones, with their bases connected by a short cylinder.—Patent completed.

1431 H. BESSEMER, Cannon-street. *Manufacture of iron.* Dated May 10, 1869.
This consists, first, in certain modified forms of the reverberatory furnace, and in each and every of such modifications the inventor employs an outer shell or casing constructed of plates of iron or steel, securely riveted together, or of cast iron secured by hoops, bolts, or ties of malleable iron or steel, the shell in either case being well caulked and rendered airtight at all laps and joints, and of sufficient strength to resist safely an internal pressure of one or more atmospheres in excess of the external atmospheric pressure.—Patent completed.

1432 H. BESSEMER, Cannon-street. *Furnaces.* Dated May 10, 1869.
This principally consists in fusing malleable or wrought iron or steel, and also pig or other carburets of iron in furnaces, where the gaseous products of combustion within the furnaces are retained under a pressure much greater than that of the external atmosphere, but which gaseous products are not in excess, but somewhat less than the pressure of the atmosphere, which immediately surrounds the exterior of the furnace or some parts thereof, the difference being only such as will cause a powerful draught or current of air to pass through the fuel in such furnaces.—Patent completed.

1433 H. BESSEMER, Cannon-street. *Converting crude into homogeneous iron.* Dated May 10, 1869.
The inventor makes the converting vessel of great strength, securely riveting and caulking all the laps and joints, so as to render it as nearly airtight as possible. He by preference forms the mouth of the vessel circular instead of oval, and of a smaller size than usual, lining the mouth with a single ring of well-burnt fireclay or composition of clay and plumbago, and he forms the metal part of the mouth of the converter with a movable dovetailed flanged ring, so that the fireclay mouth of the vessel may be readily taken out and renewed by unbolting or uncottering the iron ring which retains it in place.—Patent completed.

1434 H. BESSEMER, Cannon-street. *Treating pig iron.* Dated May 10, 1869.
This consists of a method or methods of carburising or further carburising molten pig iron after it leaves the blast furnace, and prior to its solidification, and also the further carburation of molten scrap or other wrought or malleable or puddled iron or steel that has been fused in high-pressure furnaces, as described in the specification of a patent granted to the same inventor dated November 10, 1868 (No. 3,419), or by other means, and which treatment may also be made to in part purify the iron of sulphur or other deleterious matters simultaneously with the carburising process.—Patent completed.

1435 H. BESSEMER, Cannon-street. *Blast furnaces.* Dated May 10, 1869.
The outer shell or case of the furnace is made of very strong plate iron or steel, which extends from below the bottom of the hearth up to the crown or top of the furnace, there uniting with the metal ring which forms the mouth of the furnace and thus encasing the whole of the firebrick or stonework which constitutes the furnace, suitable openings being left in the shell. The inventor prefers to make the shell in separate rings or sections united by stout flanges, by means of which the several portions are firmly united, the whole being, as far as needful, strengthened by hoops, angle ribs, or T-irons, securely riveted to the plating, the general structure being further supported on cast iron or riveted plate iron columns surrounding the lower part, all the joints of the sheet being well caulked, and capable of resisting an internal pressure of 20 or more pounds per square inch on the whole internal surface of the furnace.—Patent completed.

1436 J. HALL, Birmingham. *Firearms.* Dated May 11 1869.
This consists in making the plunger of metal with a conical or rising shoulder, on the under side of which a metal rod or pin is made to impinge by the action of the main spring of the lock (when are bounding lock is used), the plunger being made to act through a hollow nipple or other space formed for the purpose, and the breech butt being bored through so as to allow of the free passage and the up and down movement of the pin actuated by the main spring.—Patent completed.

1437 E. BRENNAN, Manchester. *Polishing threads.* Dated May 11, 1869.
This consists in employing improved rollers in connection with an improved arrangement for raising the top roller for stretching the material. The inventor forms each of the improved rollers with a number of ribs or corrugations, and places the rollers in front of the revolving brushes, the corrugations being for the purpose of allowing the bristles of the brushes to pass between the threads and open and spread them very effectually.—Patent abandoned.

1438 C. CROSS and A. HEYWOOD, jun., Manchester, and G. D. and T. B. WILSON, Cressbrook, Derbyshire. *Velocipedes.* Dated May 11, 1869.
This consists, first, in the application to the velocipede of toothed gearing for multiplying the revolutions of the driving wheel, and, second, in an improved arrangement of velocipede with three or more wheels.—Patent completed.

1439 T. DUNN, Pendleton, Manchester. *Velocipedes.* Dated May 11, 1869.
The inventor applies a ratchet wheel or other equivalent to the hind wheel of the velocipede. This ratchet wheel is worked by a catch jointed to a lever which is moved up and down by the foot of the operator. By this means the operator can get on the velocipede when it is stationary, and by working the catch lever he can then cause the velocipede to advance slowly for a certain distance, or until it has acquired the desired speed for working by the ordinary treadles.—Patent abandoned.

1440 W. R. LAKE, Southampton-buildings, Chancery-lane. *Detergent compound.* (A communication.) Dated May 11, 1869.
The gas, on being generated in the retorts, is mixed with a large quantity of impurities, chiefly ammoniacal gases, tarry vapours, sulphites, sulphides, phosphides, and others. In order to separate from the gas the ammoniacal and tarry vapours, it is passed first through a cylindrical vessel partially filled with water, and called the "receiver," and then it is passed through the "condenser." The water contained in the receiver and condenser absorbs the largest portion of the ammoniacal and some parts of the other vapours mixed with the gas, while the tarry vapours are condensed and precipitated in the form of tar.—Patent completed.

1441 C. D. ABEL, Southampton-buildings, Chancery-lane. *Galvanic batteries.* (A communication.) Dated May 11, 1869.
This consists in an improved construction of economic galvanic battery combining with a minimum of volume a maximum of intensity or of durability, and in which no evolution of nitrous or other gases takes place. The battery is, furthermore, of a more regular action than the best batteries now used, and is not subject to wear when the circuit is broken, thus effecting a saving of zinc.—Patent completed.

1442 B. LATHAM, Westminster Chambers. *Sewer ventilators.* Dated May 11, 1869.
This consists in so arranging spirally or otherwise arranged channels or passages inside the ventilating chamber containing charcoal or other deodorising material, that while any water that enters the ventilator can pass freely through such channels or passages down into the sewer without coming in contact with the deodorising material, yet any noxious gases passing up through such channels will be brought into contact with the deodorising material before issuing from the ventilator.—Patent completed.

1443 B. J. B. MILLS, Southampton-buildings. *Casting under pressure.* (A communication.) Dated May 11, 1869.
This consists in the use of a rotary wheel or cylinder, on the periphery of which are arranged a series of moulds, each formed of a pair of hinged metallic plates, which, while the casting is being performed, are held firmly together between stationary housings, suitable rollers being interposed between the rotary mould plate and the stationary housings to reduce the friction. Each of the mould plates is provided with one or more springs, which, as the rotation brings the moulds successively opposite recesses in the housings, cause the mould plates to separate with a sudden movement, causing a jar, which effectually detaches and discharges the casting.—Patent completed.

1444 J. A. MARDEN, Boston, U.S. *Steam engines.* Dated May 11, 1869.
This consists in the adoption of one or more shallow vanes or blades affixed to arms swivelled to a revolving disc mounted upon a tubular shaft supported in suitable bearings, and carrying a sliding spindle connected with the engine valve by an intermediate lever and weighted connected rod and engine valve, the whole being so arranged that friction upon the blades, induced by contact with the atmosphere, against which they are driven by the revolution of their supporting disc they shall govern and control in combination with the weighted lever the longitudinal movements of the spindle and of the weighted rod and engine valve.—Patent completed.

1445 J. B. PAYNE, Chard. *Roller blind fittings.* Dated May 11, 1869.
The fittings for roller blinds, which form the subject of the present invention, comprise a novel mode of coupling, joining, or connecting together the ends of the cord which passes round the pulley on the end of the blind roller, and also the pulley attached to the rack or tension slide below the object. As regards roller blind cords the chief object of the invention, as adapted to roller blinds, is to dispense with sewing or connecting the ends of the cord by means of thread, as is now the case.—Patent completed.

1446 L. WRAY, Ramsgate. *Quartz crushing.* Dated May 11, 1869.
The crushing instruments consist of a heavy metal block, which is mounted on a horizontal rocking shaft supported in adjustable bearings. This grinding and crushing block oscillates between two fixed jaws, the working or crushing surfaces or cheeks of which (as also those of the fixed jaws) are made, by preference, of steel or other very hard metal or substance, and are secured to the block and fixed jaws.—Patent completed.

1447 A. VICKERS, Old Broad-street. *Connecting railway rails.* (A communication.) Dated May 11, 1869.
This relates, first, to an improved mode of connecting together the rails of railways, by the adoption of which

no holes are required to be punched through the neck or web of the rail. Second, to the construction of a continuous permanent base or support for the rails of railways.—Patent abandoned.

1448 A. HENRY, Edinburgh. *Breechloaders.* Dated May 11, 1869.

This consists in employing a hollow breech cavity, similar to those specified under letters patent previously granted to the same inventor, but in place of the breech-piece being arranged as therein set forth an opening is made in one side of the breech cavity, through which the breech-piece, which is hinged or jointed to the bottom of the breech cavity, protrudes the protruding part, constituting a thumb or finger-piece, by which the breech is opened or closed.—Patent completed.

1449 C. H. MERRITT, Brunswick-square. *Basting apparatus.* Dated May 12, 1869.

The butter, fat, dripping, or other material to be used for basting is placed in a vessel, by preference of an inverted cone shape, the top or base of the cone being provided with apertures having hinged covers, through which the basting material is introduced. Near the apex of the cone and inside of it there is a grating, on which the basting material rests, from whence it flows, and is led through pipes to the article or articles to be basted, the flow being regulated by a valve or valves placed in the pipe or pipes leading therefrom. Through the centre of the vessel a tube is passed, which is intended to receive the cord or chain supporting the ordinary bottle jack or article being roasted, the basting vessel itself being suspended by a chain hooked to the lid, and, by preference, placed over the neck of the bottle-jack, when such is used. —Patent completed.

1450 J. ROBEY, Newcastle-under-Lyme. *Sugar refining.* Dated May 12, 1869.

This consists in the use and application of a decoction of tannin or Gallo-tannic acid, prepared in any suitable way from oak bark, valoinas, or other vegetable products, (which may be prepared in the same manner as the tannin used by tanners), and which is mixed in suitable proportions with the unsound syrups, sweet waters, or raw sugar in the melting pan or blow-up, and melted in the usual way.—Patent abandoned.

1451 E. T. HUGHES, Chancery-lane. *Tea and coffee urns.* (A communication.) Dated May 12, 1869.

The urn is formed with a chamber at its top entirely around its edge, space being left in the centre for the insertion of a cylinder with a perforated bottom, and of another and shorter cylinder with a perforated bottom, which serves as a sprinkler.—Patent abandoned.

1452 P. W. and W. FLOWER, Great Winchester-street-buildings, E.C. *Producing impressions on tin, &c.* (A communication.) Dated May 12, 1869.

This relates to the printing or producing impressions upon tin and terne plates and sheets of iron or other metal, covered with a coating of paint or varnish, or other coating material that will resist heat, or without such coating. And also to the use of a stove or drying oven of a new construction, specially adapted for practically carrying out the method above referred to.—Patent completed.

1453 H. ING, St. John-street-road. *Book clasps, &c.* Dated May 12, 1869.

This consists in making such fastenings or clasps expanding, flexible, and elastic by constructing them of a series of semi-cubular or trough-shaped pieces of metal interlocked and in combination with spiral or other springs, either inside or outside.—Patent abandoned.

1454 J. B. HANDYSIDE, Glasgow. *Wheels.* Dated May 12, 1869.

The wire or rim of the wheel is connected to the central boss or hub by two discs or annular plates of malleable iron or steel, these discs being put together so as to clasp between them, and in concavities formed in them for the purpose certain duplex annular projections formed on the rim or tyre and on the boss or hub respectively.—Patent completed.

1455 T. BULLIVANT, Ledbury-road, W. *Window sashes.* Dated May 12, 1869.

This consists in the employment of plain guides in which the projections at each end of such guides are dispensed with, thereby obviating the necessity of a groove deeper than the width of the guide in which to receive it when it is disconnected from the sash.—Patent completed.

1456 H. ROBINSON, Skipton, Yorkshire. *Kilns for limestone.* Dated May 12, 1869.

The kiln is composed of a top central cone together with two lower cones communicating with the top central cone on its lower side. The fuel is supplied by a separate passage or passages proceeding from the top or upper surface of the kiln and opening into the lower cones.—Patent abandoned.

1457 J. L. GREATOREX, East Grinstead. *Urinals.* Dated May 12, 1869.

This consists in so constructing the slab and overflow that they form their own trap and stand permanently half filled with water. They are thus enabled to effect the irrigation of the whole of the interior parts of the basin and back by means of perforations or openings in the hollow moulding and rim of the basin. At the soffit of the top moulding the inventor provides a guide to prevent any spray of water from the perforation at the soffit. —Patent completed.

1458 P. W. FLOWER, Neath, H. NASH, Liverpool, and R. HEATHFIELD, Birmingham. *Coating metal.* Dated May 12, 1869.

This consists in combining sheets of iron or of other metal together at their edges by any of the ordinary means before they have been coated, or such connecting of the sheets together may be only temporary where it is desired simply to obtain the advantages of a more continuous process of dipping a series of plates or sheets into a coating fluid. The joined or connected series of plates or sheets are then immersed in succession into the bath of melted metal or other substance with which they are to be coated.—Patent completed.

1459 J. H. JOHNSON, Lincoln's Inn-fields. *Saw teeth.* (A communication.) Dated May 12, 1869.

In place of treating each tooth separately by a hammer and file a dressing machine, extending over a considerable number of teeth, or, indeed, over the entire number if required at one and the same time, is employed, and the same treatment is extended to each tooth simultaneously, thereby avoiding any difference and creating complete uniformity.—Patent completed.

1460 F. R. A. GLOVER, Brading, Isle of Wight. *Anchors and gear.* Dated May 12, 1869.

The inventor attaches to the shank of the anchor, at some point near the centre of gravity, a chain or painter, whereby the anchor may be lifted and turned on this centre, on which it may be suspended in equilibrium.—Patent abandoned.

1461 A. V. NEWTON, Chancery-lane. *Expressing juices.* (A communication.) Dated May 12, 1869.

A rolling action of the pressing surfaces is adopted, derived from two cylinders set eccentrically one within the other. These cylinders are carried by antifriction rollers, which turn in rings that form loose bearings for them.—Patent abandoned.

1462 W. F. DE LA RUE, Bunhill-row. *Paper water mark.* Dated May 12, 1869.

The inventor makes a dandy roll with a sunk-in place of a raised pattern upon it and finds that the soft pulp enters the depressions of this roller so as to make a thicker paper at the parts corresponding with these depressions, whilst the paper is left elsewhere of a uniform and even thickness.—Patent completed.

1463 V. DE STAINS, Shepperton Villas, N. *Bicycle wheels, treadles, and brakes.* Dated May 13, 1869.

This relates, first, to a wheel composed of three distinct parts, viz., an outer circle, a nave, and a number of spokes connecting the two, and so disposed as to bear each singly in its turn the whole weight carried by the wheel.—Patent completed.

1464 E. V. NEWTON, Oxford-street, and P. M. CRANE, Manchester. *Coating ships.* Dated May 13, 1869.

This consists in the employment of paraffin as the basis of a composition or compound to be used for coating ships, boats, and other surfaces, to protect them and to prevent their fouling.—Patent completed.

1465 J. TIMMINS and J. GAYTON, Birmingham. *Lever fastening.* Dated May 13, 1869.

This consists, substantially, of a bent lever fitted with a cross pin in about its middle part, and which forms the axis upon which it works. The upper end of the lever is grooved or spread open so as to form a kind of prong or fork, and is for the reception of the cord or cable employed, the other end of the lever pressing the card against the frame provided when the lever is in use, and so holding it securely in a state of tension.—Patent completed.

1466 H. LUKE, Manchester. *Window sashes.* Dated May 13, 1869.

This consists in dispensing with the cords, pulleys, and weights usually employed to counterbalance window sashes, and in employing in lieu thereof a spring shot bolt or other equivalent, with an antifriction bowl at its end acting in an inclined groove in the window frame when the shot bolt is attached to the sash, or in the window sash when the shot bolt is attached to the window frame.—Patent completed.

1467 W. A. LYTTLE, Hammersmith. *Electro-telegraphic apparatus.* Dated May 13, 1869.

The inventor employs in the instrument known as the Morse printer or embosser two separate levers with an inking roller, inking point, pen, or embosser to each, one of the levers being terminated with a soft iron armature, and the other with an armature of magnetised steel or iron kept constantly polarised by the proximity or contact of a permanent magnet, and each lever having its armature end adjusted suitably for attraction by one or more electro-magnets placed underneath.

1461 T. G. F. DOLBY, Forest Gate. *Feeding bottle valve.* Dated May 13, 1869.

This consists of a tapered or conical piece in metal or other suitable material, and of a piece of sheet or moulded india-rubber or other elastic material fitted upon the tapered or conical piece, so that when the piece of india-rubber is at the thicker end of the tapered piece the valve is closed, and when the piece of india-rubber is at the thinner end the valve is opened.—Patent completed.

1462 J. TOWNSEND and P. FORBES, Glasgow. *Refining oils.* Dated May 13, 1869.

This consists in redistilling the oil or fat by means of saturated steam of high pressure, that is (to say, of a pressure of 60lb. or upwards per square inch, such steam being partly blown into the oil or fat, and partly applying its heat thereto by closed pipes, jackets, or the like, whilst direct fire heat is entirely avoided.—Patent completed.

1470 I. and G. BATTINSON and T. WHITEHEAD, Halifax. *Combing wool.* Dated May 13, 1869.

This consists in placing, when constructing new machines, the small circles nearer the large circular comb, and the dabbing brush is so arranged that a portion of the wool (being combed or operated upon) is forced upon the small circles or combs, such wool or fibre being part of or intermingled with that on the larger comb. The tensional strain exerted on the wool or fibre by the rotation of the large circle or comb draws on the small circles or combs, and imparts the necessary rotary motion on their bearings without the wheels and shafts or spindles and stud, as heretofore employed for the purpose.—Patent completed.

1471 J. FAWCETT, Huddersfield. *Measuring oil.* Dated May 13, 1869.

This consists in the employment of a supply cistern, which, by preference, the inventor furnishes with an ordinary ball tap or self-acting tap for regulating the inlet thereto of the oil or other liquid. Also in a series of enclosed measures or vessels of any required capacity, so arranged either underneath the cistern, or by its side, in such manner that the oil or liquid will gravitate or flow from the cistern into the measures when at liberty to do so. A tap or cock suitably constructed is applied to each measure, with pipes to connect them respectively with the cistern.—Patent completed.

1472 C. FERGUSON, Glasgow. *Washing, brushing, and filling bottles.* Dated May 13, 1869.

Each set of six quart bottles are first ranged or placed in a portable case or box, at equal or fixed distances apart, as in a circle equally divided round it. Each bottle is set in a good deep socket of its own, projecting up from the bottom and having a movable round supporting piece or bottom, by preference covered with a thin sheet of india-rubber. The shoulders of the bottles come up through the holes in the portable light loose lid or cover, the holes being ranged in a circle in the cover, for being brought down over the necks of the bottles, and then temporarily fixed to the box by the swivel bolts or latches, taking into recessed notches or catches on the lid and sides of the box respectively.—Patent completed.

1473 J. BOWNES, Mansfield. *Steaming tobacco.* Dated May 13, 1869.

This consists in the employment for that purpose of a steam jacketted cylinder, mounted upon a suitable supporting surface, and provided internally with a pressing piston, which works from below upwards.—Patent abandoned.

1474 A. FRIEDMANN, Hatton Garden. *New ornament.* Dated May 13, 1869.

The ornament is formed of two separate parts or pieces which are fitted, connected, or fastened together by snap, catch, or other connecting contrivance, so that they are capable of being readily connected with and disconnected from each other.—Patent abandoned.

1475 W. CADOGAN, Birkenhead. *Coupling for driving straps.* Dated May 13, 1869.

In order to connect together the two ends of a driving strap, the inventor attaches to the back of the belt at both of its ends by rivets, screws, and nuts, or otherwise, a plate of metal. The back of each plate has standing out from it a row of studs, each stud carrying a pulley grooved around its circumference; above the pulleys is a bar or narrow plate, to which the tops of the studs are fixed, and this bar or narrow plate is attached at its ends to the two ends of the plate, which is fixed to the end of the strap. Each end of the strap is thus furnished with a row of pulleys at its back.—Patent completed.

1476 W. STEPHENSON, Sculcoats, Yorkshire. *Facilitating consumption of smoke.* Dated May 13, 1869.

This consists in fitting a cylindrical or other shaped reservoir at or near the front of the furnace. In this reservoir the inventor fits a vessel having a valve opening inwards in the bottom of it. The upper part of this vessel is connected by a series of rods and levers to a door or valve set in the brickwork at or near the bridge at the back of the furnace.—Patent abandoned.

1477 I. and J. H. STOREY, Manchester, and H. LEA and T. LANE, Birmingham. *Controlling discharge of water.* Dated May 14, 1869.

On the stand, pipe, or fountain the inventors employ a valve, the inlet orifice of which is closed by a diaphragm, acted upon by the pressure of the water when admitted to the back of the diaphragm. The space at the back of the said diaphragm is in communication with a small valve, which when opened relieves the back of the diaphragm from the said pressure, and thus permits the discharge of water from the main valve.

1478 J. and J. KIPPAX, Bolton-le-Moors. *Weaving counterpanes.* Dated May 14, 1869.

The quilts are woven with the aid of healds and of jacquard apparatus, and with designs or patterns either geometrical or figured. Two warps are employed, the face warp having twice as many ends as the back warp. —Patent abandoned.

1479 C. W. LANCASTER, New Bond-street. *Concentrating shot.* Dated May 14, 1869.

The inventor employs over the shot and under the ordinary terminal wad of the cartridge a hollow cylindrical wad formed of a short piece of cylinder of paper or other material closed at the end by the insertion of an ordinary cloth or other wadding or by a terminal wad. This short cylinder the inventor forms to fit inside the cartridge case, and he inserts it after putting in the shot, so that it forms a cup or thimble over the front portion of the charge of shot. This hollow wadding is then secured in its place by the ordinary terminal wad, over which the cartridge case can be turned.—Patent completed.

1480 J. T. GRIFFIN, Fleet-street. *Knives and forks.* (A communication.) Dated May 14, 1869.

The objects are, first, to manufacture the blades, bolsters, and tangs of table and dessert knives and forks of separate pieces of metal, and, second, to form the handles of one or different materials, in order that when complete they may present a novel and ornamental appearance. The blades are made by casting or otherwise, and a notch or recess is formed in the handle thereof, in order to fit the handle thereto.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated November 23, 1869.

3376 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved steam boiler supply cock.

3377 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in electro-metallurgy.

3378 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in electric batteries.

3379 S. G. Arnold, Southampton-buildings, Chancery-lane. Improvements in saws and saw teeth, and in machinery for manufacturing the same.

3380 J. E. Croce-Spinelli, of Paris, Rue de Rome. Improvements in nautic means and apparatus.

3381 E. Round, Sheffield. An improved indicator.

3382 W. E. Gedge, Wellington-street, Strand. An improved system of hydraulic traction on railways and other roads.

3383 H. F. Shaw, West Roxbury, Norfolk, Massachusetts, U.S.A. Improvements in cutters for moving machines.

3384 A. Nairn, Leith, Midlothian. Improvements in steam carriages for common roads, and in part applicable to railway locomotives.

3385 F. Foster, Lansdowne Cottage, Essex-road, Islington. Improvements in pressure gauges.

3386 J. H. Johnson, Lincoln's Inn-fields. Improvements in machinery or apparatus for grinding saws.

3387 H. C. Lobnitz, Renfrewshire. Improvements in motive-power engines.

Dated November 24, 1869.

3388 A. M'Neill, Liverpool. A safe for ships and other navigable vessels carrying mails, specie, and other valuables.

3389 F. J. Granville, Glencrutcherry, Douglas, Isle of Man, and H. Gardner, Elm Bank, Oakfield, Liverpool. Improvements in advertising sheets or papers, being an improved means of advertising, and in apparatus for the production of such advertising papers.

3390 W. Thomas, Llanelly, Carmarthenshire. Improvements in obtaining power.

3391 J. Fogg, Edgeworth, Lancashire. Improvements in machinery for dressing flags and stone, and other hard materials.

3392 S. Cotton, Belfast, Ireland. Improvements in machinery for preparing flax, hemp, worsted, silk, and other fibrous substances.

3393 J. Norris, Manchester, and E. Longworth, Winewall, near Colne, Lancashire. Improved self-acting apparatus for placing fog signals upon railways.

3394 J. Dunkerley, Audenshaw, Lancashire, and B. Dunkerley, Stockport, Cheshire. Improvements in machinery or apparatus employed for felting or planking the bodies of hats, bonnets, or other coverings for the head, which machinery is also applicable for felting woollen cloths.

3395 J. B. Paddon, Hove, Sussex. Improvements in apparatus used in the manufacture of gas.

3396 D. Miles, Boston, Massachusetts, U.S.A. An improved mode of, and apparatus for, lighting and extinguishing gas by electricity.

3397 J. Turnbull, Edinburgh. Improvements in connecting and disconnecting carriages and waggons on railways, and in the apparatus connected therewith.

3398 S. Chatwood, Bolton, Lancashire, and T. Sturgeon, Manchester. Improvements in apparatus for forcing and drawing fluids and liquids.

3399 M. Henry, Fleet-street, City. Improvements in apparatus for moving or transporting railway carriages and other heavy bodies from place to place.

3400 J. Downs, Kingston-upon-Hull, Yorkshire. Improved hydraulic presses used for seed-crushing, oil expressing, and other similar purposes.

3401 W. C. Mann, Leeds. Improvements in the manufacture of hats and in the machinery used therein.

Dated November 25, 1868.

3402 P. C. Evans, Brimscomb Mills, Gloucestershire, and H. J. H. King, Glasgow. Improvements in apparatus for feeding wool, cotton, or other fibrous materials to carding or other machines.

3403 F. W. Webb, Bolton, Lancashire. Improvements in locomotive and other steam engines and boilers, parts of which are applicable to riveted work and railway rollin stock in general.

3404 T. Richardson, Manchester Improvements in the construction of compound forms and desks or tables for schools and other similar purposes.

3405 J. Nichols, Pendleton, Salford. Improvements in machinery for polishing yarns and threads.

3406 B. Goddard and W. Finley, Stockport, Cheshire. Improved machinery for pill mass mixing and pill making, mixing plastic substances, making plaster rolls, and for other similar or analogous purposes.

3407 E. F. Goodall, Birmingham. Improvements in excise inkbottles, and other ink bottles and inkstands.

3408 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for propelling ships.

3409 B. Johnson and E. B. Ellington, Chester. Improvements in hydraulic cranes or apparatus for moving weights.

3410 A. M'Dougall, Manchester. Improvements in the manufacture of blacking.

3411 T. Brown, Newgate-street, City. Improvements in the construction and arrangement of machinery or apparatus for drilling or boring rocks or other analogous substances.

3412 L. Mount, Bromley-by-Bow. Improvements in machinery or apparatus for filling match splints or other splints, whether made of wood, wax, glass, or of any other material.

3413 J. Keats, Leek, Staffordshire. An improved manufacture of buckle.

3414 G. M. Felton, Well-street, City. Improvements in collars, cuffs, and other similar articles.

3415 W. E. Gedge, Wellington-street, Strand. The composition and application of a novel powder for destroying the oidium in vines and other plants, and the application of a mixture of some of its ingredients in a liquid state to destroy parasites between the bark and wood of trees.

3416 W. Pollitt, Charlotte-street, Blackburn, and W. J. Knowles, Alton-street, Blackburn, Lancashire. Improvements in machinery for washing, wringing, mangling, churning, and mixing fluids.

Dated November 26, 1869.

3417 D. Barker, Northfleet, Kent. Improvements in the manufacture of varnish and varnish paints.

3418 J. Denis, Great Dover-street, Surrey. Improvements in the means of, and machinery for, producing pulp from wood and other fibrous substances for the manufacture of paper.

3419 J., J., and W. Fletcher, Eagle Foundry, Salford, Lancashire. Improvements in, and applicable to, mortar mills, and other machines of the like nature for grinding or pulverising.

3420 S. Tatton, Stockwell-street, Leek, Staffordshire. An improved manufacture of reels, bobbins, and other similar articles.

3421 S. Tatton, Stockwell-street, Leek, Staffordshire. An improved card for facilitating the withdrawal of single threads for sewing purposes.

3422 E. H. Burke, King's Bench Walk, Temple. Improvements in metallic barrels.

3423 B. Wood, Wordsley Foundry, Stourbridge, Worcestershire. Improvements in the manufacture of lids for railway axle boxes.

3424 W. Perkins, Herne Hill, Surrey. Improvements in fusees, matches, or other analogous articles, and in the holders for the same.

3425 J. Combe, Belfast. Improvements in machinery for hackling flax and other fibrous substances.

3426 A. C. Engert, Tabernacle-row. Improvements in the manufacture of ornamental placards, show cards, labels, maps, and such like articles.

3427 J. Brunton, Kensington. Improvements in working and locking railway points and signals.

3428 S. Wyatt, Old Town-street, Plymouth, Devonshire. Improvements in the preservation of meat and in the apparatus employed therein.

Dated November 27, 1869.

3429 H. S. Freeman, Fenchurch-street, City. Improvements in the method of effecting the more perfect adjustment of men's wearing apparel.

3430 F. Preston, Manchester. Improvements in machinery or apparatus for preparing, spinning, twisting, and doubling wool, cotton, and other fibrous substances.

3431 W. C. S. Percy, Manchester. Improvements in machinery or apparatus for cutting animal and vegetable substances, and for making pies and sausages.

3432 A. Barclay, Kilmarnock, Ayrshire. Improvements in condensers, and in ejecting or withdrawing liquids and fluids therefrom, and in apparatus connected therewith.

3433 G. Bertram, Edinburgh, and M. Patterson, Ivy Bridge, Devonshire. Certain improvements in apparatus for straining paper pulp.

3434 J., J., E., and W. Pitt, Cleckheaton, Yorkshire. Improvements in machinery, or apparatus for drilling, turning, or cutting and shaping metals or other materials.

3435 L. Pochet, Vendome (Loire et Cher), France. An improved apparatus for cutting or dressing stone.

3436 W. Johnson, Gough-square, City. An improvement in lock fastenings for expanding cases and boxes.

3437 J. Howard and E. T. Bousfield, Bedford. Improvements in apparatus for cutting standing crops and collecting the same when cut.

3438 A. E. Loram, Birmingham. Improvements in buckles and clasps.

3439 W. Cross, Glasgow. An improved manufacture of shawls.

3440 G. Lockett, Red Lion-square, Holborn. A revolving graphoscope.

3441 W. Brookes, Chancery-lane. Improvements in sewing machines.

3442 B. Oldfield, Coventry, Warwickshire. Improvements in looms, and in devices to be employed therewith for weaving.

3443 S., J. J., and L. H. Perry, Red Lion-square. Improvements in boxes for holding various articles.

3444 S. Fox and J. Reffitt, Silver Cross Works, Leeds. Improvements in machinery or apparatus for boring, turning, and polishing treenails, bobbins, or other similar articles of wood or other materials.

Dated November 29, 1869.

3445 J. Moseley, Manchester. Improvements in the manufacture of calico-printers' blankets.

3446 G. B. M'Farland, New York, U.S.A. A convertible double-centre rotary engine, so called M'Farland's rotary engine.

3447 E. Lethbridge, Benson, Oxfordshire. Improvements in the means of, and apparatus for, balancing millstones.

3448 J. Williams, jun., King's-road, Chelsea. A new or improved apparatus for toasting, roasting, and cooking.

3449 J. Tester, Hurst Green, Sussex. Improvements in machinery for cutting chaff and other similar vegetable substances.

3450 E. Oades, Egham, Surrey. Improvements in vent plugs.

3451 T. Reissig, Manchester. Improvements in making a new derivative of phenol, and in producing certain colours therewith upon textile fabrics and yarns.

3452 J. C. Mewburn, Fleet-street, City. Improvements in obtaining motive power, and in apparatus employed therein.

3453 H. Draper, Bebington, Cheshire. Improvements in apparatus to be used when tanning hides and skins.

3454 G. and A. B. Marquis, Glasgow. Improvements in machinery for cutting or dividing metal or other sheets.

3455 J. Edwards, Bridge Cottage, Farrington, near Preston, and J. Quin, Golden Hill, Leyland, near Preston, Lancashire. Preventing roller laps on roller ends of machines for carding cotton, woollen, flax, or any other fibrous material.

3456 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in journal bearings for railway carriages, and in the means for lubricating the same.

3457 W. Parham, Northgate-street, Bath, Somersetshire. Improvements in the construction of horticultural and other buildings and structures.

3458 J. Speight, Bradford, Yorkshire. Improvements in machinery or apparatus for spinning, twisting, and roving worsted or other fibrous substances.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," November 30, 1869

1831 R. S. Bakewell
2147 W. R. Lake
2154 B. Russ
2159 H. E. Newton
2164 A. Ancion
2169 W. Furness
2186 T. Holt
2197 H. Higgins and T. S. Whitworth
2206 G. Follett

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C. to whom all communications upon the subject should be addressed.

THE

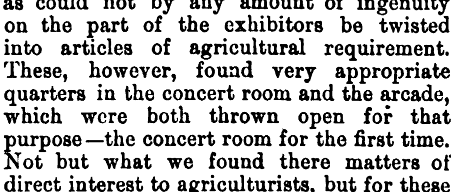
MECHANICS' MAGAZINE.

LONDON: FRIDAY, DECEMBER 10, 1869.

THE SMITHFIELD CLUB SHOW.

FOLLOWING so closely upon a show of such unparalleled magnitude as that of the Royal Agricultural Society at Manchester in July last, at which the various makers had full opportunity of putting forth all their resources, the present Smithfield Club Show becomes rather dwarfed in its dimensions. But we must not compare it with such a display as Manchester witnessed, but rather with its own predecessors in the Agricultural Hall at Islington. And here the comparison is more favourable, inasmuch as the exhibition of machinery and implements this year is over the average of what we usually find. At first sight we were inclined to think there was a falling off in the number of exhibits, but after a careful investigation of every stand in the building, we arrived at the conclusion that agriculture was mechanically represented rather better than usual. One thing, however, is worthy of note, and that is that the committee of the Smithfield Club have exercised a very wise discretion in excluding from the ball proper such matters as could not by any amount of ingenuity on the part of the exhibitors be twisted into articles of agricultural requirement. These, however, found very appropriate quarters in the concert room and the arcade, which were both thrown open for that purpose—the concert room for the first time. Not but what we found there matters of direct interest to agriculturists, but for these we suppose no room could be found in the main building. As, however, these two departments are constantly thronged, the exhibitors will not suffer from any absence of notice from the public. Taking the show as a whole it is devoid of any striking novelty—as far as engines and implements are concerned—although most makers, keeping pace with the times, have improved in detail here a little and there a little, so that we shall not travel from Dan to Beersheba and cry "all is barren."

Turning, then, to our mechanical friends, we first note, in proof of the position we have just advanced, one or two special features which we met at the stand of Messrs. Robey and Co., of the Perseverance Works, Lincoln. This firm exhibited several excellent engines, their special feature being their 8-horse power portable engine, in which the novelty is the method of producing variable expansion of the steam. This is done in a very simple and efficient manner by the governor, of



which we annex a cut. The governor is placed on the crank shaft, and revolving with it is of course affected by the slightest difference in the speed. The valve eccentric has a rectangular slot cut parallel to a line connecting its two centres of forward and backward motion. This fits upon a square on the crank shaft, upon which it slides at right angles to the crank, being held in position by two wedges which are fastened to the governor slide, as seen in the sectional part of our cut. Upon the governor balls expanding the wedges are drawn out, the travel of the valve is reduced, the cut-off is made earlier, while the lead remains constant. The range is from $\frac{3}{4}$in. to $\frac{1}{8}$in.; the 8-horse engine, with 60lb. steam, developes 19-horse power indicated when cutting off at $\frac{1}{3}$in., with a consumption of coal of 60lb. per hour, being equivalent to a trifle over 3lb. per horse power per hour. The cylinder of this engine is steam jacketed, and part of the exhaust is taken to heat the feed water. Messrs. Robey's vertical engine is of 4-horse power, and is strongly fixed on to the boiler, and the whole firmly fixed on a cast-iron foundation plate, which also serves as ashpan and water heater. Besides these engines, we have to notice a thrashing machine and a straw elevator by the same firm. A novel and valuable feature has been introduced in the thrashing machine The frame is made of angle iron riveted up, instead of wood as is the general practice. The advantage of this is obvious in hot climates on account of shrinkage and twisting, whilst generally it is better, being more rigid and durable without being heavier. The straw elevator is noticeable for the ease with which it can be set to work at any angle to the thrashing machine and the very simple method adopted for driving.

At the stand of Messrs. J. and F. Howard, of the Britannia Ironworks, Bedford, we found a new patent self-acting horse rake and a new double-furrowed plough which they have just brought out, and which were exhibited for the first time. The new horse rake —of which an elegant working model was shown beside the full-sized implement—is evidently the result of much thought and careful trial. In preference to any other more costly and complicated device, a simple brake is adopted, which, when put in action by the driver's foot, instantly raises the teeth. This plan has the signal advantage over other self-acting plans, that the teeth can be dropped into work momentarily, or held out of work at the will of the driver. In other words, the action is not dependent upon the revolution of any rochets or complicated lifting machinery, but is under the control of the man. By this arrangement, the foot of the man has not to travel with the lever movement; the driver has simply to touch the lever to put it into action, and the removal of the foot instantly throws it out. The leverage is so arranged that it can be worked by the driver walking behind the implement as well as when riding on the seat. In the new double-furrow plough the beams —as in the steam ploughs of this firm—are of double-ribbed steel, firmly braced and riveted together. The frames are of malleable iron, which has the advantage of being as tough as wrought iron, and as stiff as cast iron. The bodies, which are attached with two bolts only, can be fixed to each side of the beams, so that the width of the furrows can be varied, and this without the firmness and stiffness of the plough being sacrificed. The difficulty in turning double ploughs at the land's end is obviated by attaching the fore wheels to a simple swing carriage of novel construction. By this arrangement, the strength of a boy only is needed to turn the implement. The plough is so arranged that the friction wheel in the rear can be removed when ploughing land which clogs. The shares are fixed on wrought lever necks upon the well-known principle patented by this firm, so that the relative depths of the furrows can be instantly adjusted. We cannot leave this stand without referring to the new patent central-axle haymaker which Messrs. Howard have been engaged in perfecting during the last three or four hay seasons. The main feature of the new machine is that the axle which carries the fork barrels is in a direct line between and not behind the wheels. By this arrangement increased strength is obtained, through the framework being outside instead of inside the wheels, and the whole being held firmly together by a central main axle. The machine will cross ridge and furrow, owing to the wheels and forks falling into the furrows or rising over the ridges at the same moment. The most fruitful cause of breakage in all former machines is that, the barrels being in the rear, they come into contact, not simply with the grass, but with the ground when working over unlevel land. The liability to load when tedding newly-mown grass—so great a drawback in other machines—is avoided, inasmuch as the frame is outside the wheels, and the axle boxes are not stationary, but like the other parts revolve—in other words, there is no dead surface for the grass to lodge upon. Messrs. Howards' safety tubular boiler, which has been illustrated and described in our pages, continues to give every satisfaction and is coming largely into use.

Messrs. E. R. and F. Turner, of Ipswich, showed their portable steam engines, which possess the distinctive features of the manufactures of this firm, viz., careful design and attention to the details of construction. They are well adapted to the requirements of the users of such machines, and possess strength and durability. Any exhibit of machines by this firm would be incomplete without their crushing mills, which we found here in full force. The large variety of these mills manufactured by Messrs. Turner enables purchasers, however large or small their requirements, to find a machine suited to their wants. These mills are well adapted to prepare maize for horse food. As this material has much increased in favour for feeding purposes, we imagine the sale of these mills will receive an additional impetus. In fact, the makers inform us that the demand for these machines has this season been unusually brisk. Three varieties of oil cake breakers were also here exhibited. The cake in passing through the machine is acted on by two sets of rollers and reduced to a size suitable for lambs, with a minimum of power. The larger machine was capable of breaking down two tons per hour of the hardest cake. The horse gear which we found at this stand was mounted on a substantial oak frame, so that no further outlay is requisite on the purchaser's part, as it may be readily and securely fixed by a few stakes. The intermediate motion is provided with a clutch to start or stop the driven machine, independently of the horses. The Royal Society's 1867 first prize French burr grinding mill was also exhibited. This, with accompanying crane, was a well got up machine, and deserved attention. A small machine for shelling maize, suitable for the foreign and colonial market, concluded the exhibit on this stand. The silver medal of the exhibition at Altona, held in September last, was awarded this firm.

Messrs. Clayton and Shuttleworth, of the Stamp End Ironworks, Lincoln, made a very handsome display of engines both portable and fixed. The special features of these engines have been placed before our readers in time past, but as the detail improvements are important and cannot be too well known, we will briefly refer to them here. In the outside cylinder portable engine the exhaust pipe is on the outside of the boiler, and is formed with a branch, to which a tube is attached for conveying a portion of the steam to the feed-water, thus effecting a considerable saving in fuel. Each engine is fitted with a second safety valve under lock and key, as a further safeguard against accidents arising from inattention and carelessness. In the inside cylinder portable, the cylinder is placed in the smoke-box, surrounded by a jacket forming an annular space, which being filled with steam, heats the cylinder and at the same time protects it from the injury that would be caused by direct contact with the heated gases. By this arrangement, condensation and radiation are prevented, and economy is obtained. Both ends of the cylinder and steam chest are left exposed, so that the covers can be removed and the piston

and slide valve cleaned or adjusted as expeditiously and readily as in an outside cylinder engine. This arrangement does away with the objection generally made to engines having the cylinder and steam chest placed inside. An important feature in Messrs. Clayton and Co.'s traction engine is the self-acting differential motion, which enables the driving wheels to accommodate themselves to the sharpest curves without strain or loss of power; both wheels at the same time are kept in gear and receive the full power from the engine. The absence of this feature in a traction engine is a defect, detrimental alike to its efficiency and durability. The thrashing machines of this firm, both portable and fixed, are as perfect and efficient as every known modern improvement can make them. The rolled steel beater plates introduced by this firm are a marked success. They are found to wear three times as long as the malleable iron plates hitherto in use, and when the thrashing surface is worn away the material is available for forge purposes. The corn mills of this firm are too well known to require further remark from us than that they are of the usual excellent design and finish.

Messrs. A. and W. Eddington, of Copenhagen Wharf, Limehouse, and the New-street Ironworks, Chelmsford, exhibited a very good specimen of their work in a 7-horse power portable engine. This firm had several other entries, but owing to the space allotted to them being less than that for which they applied they were obliged to omit them from their stand. One special article which we regretted to see absent was their 12-horse traction ploughing and draining engine, which is fitted with three speeds and compensating road gear. The 7-horse engine exhibited was very strongly built, and so arranged as to be easy of access in case of repair. The starting valve is placed at the top of the cylinder, immediately over the throttle valve, and by removing one cover both are easily examined. By this arrangement the steam is admitted in a much drier state than when it is cut off inside the boiler. All the bearings are supplied with oil syphons worked in the solid metal, thereby avoiding all possibility of losing them, as is the case with loose ones. These engines are very strong, and are well adapted for continuous and heavy work. The boiler plates are of Bowling iron, and being well put together give the impression of thorough reliability, an element much needed in engines which are liable to be carelessly tended.

The old firm of Ransomes, Sims, and Head, of the Orwell Works, Ipswich, Suffolk, were well represented in engines, thrashing machines, and ploughs. To comment upon the exhibits of this firm is simply to repeat the oft-told story of their excellence. We, therefore, leave them to speak for themselves, or rather to be spoken for by the splendid trophy of medals which formed the most prominent feature of this stand. These medals were 113 in number, and filled a circular case about 30in. in diameter. They were from all parts of Great Britain and the continent; in fact, from all parts of the world. They consist of thirty-eight gold, seventy silver, and five bronze medals, forming a collection of which Messrs. Ransomes and Co. may well be proud. With regard to the portable engines exhibited by this firm, we may observe in passing that they are constructed on the expansion principle, and are well arranged for economising fuel. They are admirably adapted for countries where coal has to be imported and is, consequently, very expensive, and where wood is scarce. Two steam thrashing machines were exhibited, a double and a single blast, the latter of which obtained a prize at the Manchester Show.

Leaving for awhile the massive machinery in the basement of the Hall, we will proceed to mount to the galleries, to take a look at some old friends there. And the first to welcome us at the top of the staircase by which we made our ascent is Mr. F. B. Vallance, of 101, Cannon-street, London, and the Alicel Works, Greenwich. This gentleman exhibited the only piece of machinery in motion in the Hall, and that was the Hugon gas engine, which he is largely manufacturing, as it has come greatly into favour with the public. This engine admirably takes the place of the steam engine for occasional use; it is set to work or stopped instantly by turning a tap on or off. It is as completely regulated as a steam engine, and when desired is fitted with governors and throttle valve, but has a special regulating apparatus for feeding itself with gas, which permits the utmost variation of speed and power within reasonable limits, and gives the engine a valuable qualification for operations requiring even and regular speeds. The gas engines have been worked at speeds varying from 50 to 150 revolutions per minute; the most economical speed is about 60 revolutions per minute. The many obvious advantages offered by such a convenient and inexpensive source of motive power are enhanced by the circumstance of its safety. Insurance is not affected either in rate or amount by the insured having one of these engines on any floor of a building. Since last year Mr. Vallance has improved this engine in several details, especially in the slide gear. He has also added a very carefully worked out cam arrangement, and has applied metallic packing throughout.

Messrs. Hayward, Tyler, and Co., of Upper Whitecross-street, exhibited one of the greatest novelties in the building, and one which has already been brought before our readers in these columns. The "Universal" steam pump is one of those useful inventions emanating from American brain, of which so many have found their way across the Atlantic. Having already fully described it in the MECHANICS' MAGAZINE, we shall only briefly say that it is one of the most thoroughly mechanical inventions we have seen for a long time. At this stand is also exhibited a good display of the standard manufacture of the firm, such as deep well pumps, horse gear, well frames, a small vertical boiler with engine attached, garden and house fire engines, besides the California pumps. This firm also exhibited one of Jordan's combination boilers, which are constructed in separate segments, each segment consisting of a cylinder 7ft. 6in. long, 9in. diameter, with top and bottom chambers, giving a heating surface exposed to the flame of 16 square feet, in addition to the cast-iron parts which are out of the way of the fire—an ample allowance per horse power. The horse power is reckoned according to the number of tubes, viz., one tube to a horse power.

Passing on to the stand of Messrs. I. and T. Hepburn and Sons, of Long-lane, Southwark, London, one is forced involuntarily to exclaim "there's nothing like leather." This firm exhibited a collection of leather bands, hose pipes, and other leather articles for machine use. It is as well to draw attention to articles chiefly for agricultural use, and we name what Messrs. Hepburn and Sons appear to have made on this occasion their speciality, viz., the endless belt for transmitting the power from the portable engines. From the circumstance of their being exposed to all weathers, these belts have ever been more or less a source of trouble. When wet, they pull out of shape and run off the pulleys or are destroyed by running on the flange. India-rubber and gutta-percha have both been tried, but in neither has been found a perfect substitute. To meet this want, Messrs. Hepburn have introduced a composite double belt, the under or working side being leather, and the upper layer prepared untanned hide. These are strongly sewn together with wire, and combine the greatest tenacity and durability; they run perfectly straight, and are admitted by all who have used them to be the best band for the work. From the known excellence of Messrs. Hepburn and Sons' leather, and the opportunity they have, as tanners, for selecting suitable hides for the various purposes, they stand in no fear of their bands being rivalled.

No small share of attention was monopolised by Messrs. F. and C. Hancock, of Victoria-terrace, Dudley, whose prize medal butter purifying machine formed as great an attraction here as it did at Manchester. This machine is for the purpose of purifying butter from all traces of milk and acid, also for cooling and making it firm in hot weather without touching it with the hand. All these things it does most effectually, as we ourselves have proved. It also deprives over-salt butter of its saltness, rendering it very palatable. These machines were also exhibited close by at the stand of Mr. J. D. Hancock, of Slaney-street, Birmingham, who also had a new haymaking machine and a new horse clipper, which are well worthy the attention of agriculturists.

Messrs. Yarrow and Hedley, engineers, of Poplar, London, and well known for their steam launches, exhibited a 3½-horse power steam engine and boiler, specially useful to colonial farmers requiring to transport produce by river. This is a special class of engine to which this firm have devoted their attention; it is very simple in design, and of as high-class workmanship as can be produced. It is applicable for all purposes where power is required, equally the same as any portable or stationary engine, the main difference consisting in its being adapted for readily fixing in a boat or barge for purposes of propulsion. In districts where the produce of the farm has to be conveyed distances on rivers or canals, this application of steam power cannot fail to be of great utility.

Messrs. Coleman and Morton, of the London-road Ironworks, Chelmsford, had several examples of their prize cultivator and other agricultural implements. Their adjustable rotary corn screen and separator is a very perfect instrument, and possesses many advantages. The screen is composed of diagonally-placed bars of a triangular section, the spaces being set by an adjusting screw. This arrangement appears most satisfactory. We should add that there is an outside padded roller which keeps the meshes of the screen clear. A special feature at this stand was Walkers' patent horse pitchfork or elevator for stacking straw and hay. It is an American labour-saving invention, and by it hay or loose corn can be lifted off carts or waggons and deposited on the stack or in the barn. This implement will be found of great use where ricks have arrived at a height where the hay has to be raised overhead.

Before drawing our present notice to a close we must refer to a very ingenious and perfect self-acting brake which was exhibited by Mr. T. B. Ayshford, of the Britannia Works, Walham-green, Fulham. On quitting the building we found this brake fitted to one of Mr. Ayshford's elegant canoe waggonettes, and which acts with the greatest certainty. It consists of a chain attached to the horse collar, and which, passing round a pulley on the end of the carriage pole, is attached to a rod which runs under the pole. This rod acts on a simple lever arrangement, which puts on the brake directly the horses are pulled up, or when the carriage is going down a hill. If necessary the brake can be released at any moment by the coachman placing his foot on a stud, which brings the lever back and takes the brake off. This is unquestionably the most effective, simple, and useful of modern brakes, as a contrivance applicable to vehicles to which horses supply the dragging power. Whether in stopping or going down hill, it acts just in proportion to the weight and momentum to be overcome,

without the slightest trouble to the driver or inconvenience to the animals.

For the present we are obliged to bring our remarks to a conclusion, but shall resume the subject next week.

A UNIVERSAL TELEGRAPH.

DURING the past few weeks the public in general, and the telegraphic world in particular, have had their curiosity awakened by such announcements in the daily papers as the following:—"The Universal Telegraph," "A Telegraph for Everybody," "The Essence of Simplicity," "No Battery Required," "Highly Entertaining and Indispensably Useful," and no small amount of speculation has been exercised as to their object. On Wednesday last we were favoured with the first view of the remarkable apparatus to which these announcements refer, and which is the invention of Mr. T. W. Tobin, of the Royal Polytechnic Institution, Regent-street. We therefore, without further delay, proceed to enlighten our readers upon the subject. We cannot better enhance the value and appreciation which this invention is bound to command than by describing in detail the seance in which we took part at this our first interview. It would be presumption on our part to give to our readers the preliminary reminder we received as to the points of importance in the ordinary and cheapest form of the electric telegraph. Our object was, of course, to compare, and we were accordingly furnished with certain statements which seemed to bear on the subject in question—first, as to the complication of machinery; second, the cost and trouble of maintenance of battery; and third, the difficulty of acquiring the system of arbitrary signs for the alphabet, &c., indispensable consequent upon the simplest form of instrument in use. We had then introduced to us two neatly finished mahogany cases about 5in. × 3in. × 2in., having a handle or semaphore in front of each, and a disc or index in the rear. On the latter were painted the letters of the alphabet and other arbitrary signs. One of these instruments was attached to the termination of a metallic conductor, and the other to another (in this instance about thirty yards). It was stated at the same time by the inventor that for all practical purposes the length was immaterial, he having already used the same instruments with 1¼ miles of ordinary telegraph aerial wire. Matters thus arranged, and the return current completed by means of earth plates, gas tubing, or secondary conductors, the system was complete and ready for operation.

The semaphores, hitherto in an upright position, were now placed horizontally; immediately corresponding indices moved along the discs of the two instruments, and on arriving at any particular letter or sign were stopped instantly at a slight alteration of the semaphore by the party signalling. As true as the "needle to the pole" did the two indices work with microscopic precision and in perfect unison. When read, by a second movement of the handle both indices return to zero. Here, then, was pointed out a new feature appertaining to alphabetical instruments. Take the beautiful instrument of Wheatstone for example; once out of unison by any of a number of circumstances, so it continues until, by unintelligible signalling, it is agreed by both operators to register zero. Although we must admit there is time sacrificed for the sake of simplicity of arrangement, there is in the present case this decided advantage—almost absolute impossibility of derangement. Where now, we naturally inquired, is the battery or motive power supplying the electricity to the apparatus? Imagine our surprise when we were informed and convinced that, beyond the two instruments previously described, nothing existed to complete the entire system of telegraphy. By what means was the power, then, generated? Where the prime mover? A steam engine without a boiler would have been no less strange. But facts are stubborn things, and here the evidence stares us in the face. Of course, we expressed a desire to see the contents of one of these magic boxes. It was accordingly laid open, and equally astonished were we with the internal arrangement. It simply contained——. But we must not anticipate; being under promise of secrecy we are bound not to disclose at present what we saw. On another occasion we may find reason to revert to the subject. In the meantime the apparatus will be before the public, the instruments will probably be in every household, and will, we anticipate, become "everybody's telegraph." A telegraph complete, consisting of a set of instruments, connecting wire, and all adjuncts, is to be supplied at a price which will bring it within "everybody's" reach. Such, then, is this remarkable invention, as wonderful as it is simple. Whether as a philosophical instrument, as a commercial enterprise, or even from its cheapness as a scientific toy, it is destined to command "universal" patronage.

ON SYNOPTIC WEATHER CHARTS.

THE more we contemplate the progress of meteorology during the present century the more we become impressed with the conviction that the best mode of treating meteorological data with the object of tracing the origin, cause, and destination of the aërial currents which determine the character of the weather of any country is the graphic or symbolical method of exhibiting such data, so as to give a bird's eye view, as it were, of the state of the atmosphere over the largest possible extent of the earth's surface. This is the method upon which the cyclonists have developed the laws of tempests, from the crude data furnished by the ordinary log books of ships, in which neither winds nor weather were recorded with much regard to accuracy, while the barometers and thermometers used were generally defective and differed each from each, few, indeed, agreeing with standard instruments.

In 1857 the Meteorological Office made arrangements for giving the method an extended trial, not without reason expecting fruitful results. Observations were collected for the winter 1856-7 over the area comprised within the parallels of 40deg. and 70deg. N., and the meridians of 10deg. E. and 30deg. W., from the sea as well as from the land. Ships, lighthouses, public and private observatories, both at home and abroad, zealously co-operated and sent in their records. Therefrom it appears a series of charts was compiled exhibiting simultaneous states of the atmosphere over the British Isles and adjacent seas, especially the direction of wind current and its strength at certain times referred to the first meridian, rain also and fog, besides other features. The direction of wind was shown by a line drawn to leeward from the place of observation, in length proportioned to its strength or force. Pressure and temperature duly corrected and reduced were likewise shown, but in what manner we are not informed. Being intended to express consecutive simultaneous states of the atmosphere—as if an eye in space looked down upon the whole extent at one time, and afterwards took similar views at regular intervals of hours or days, so as to obtain sequences of synoptic conditions—Admiral Fitzroy termed them very appropriately synoptic charts. The report of the Meteorological Office for 1858 states: "Among the results already obtained from these charts is the true north and south or meridianal direction of certain atmospheric wave lines (those of the troughs as well as those of the crests), the diminution of the wind's strength or force over land, and evidence of a continuous alternation or opposition of the great polar and equatorial currents of the atmosphere." The next report of the office was presented to Parliament in 1862, and in this the subject is again alluded to as follows:—"In 1857 it was first arranged that simultaneous observations should be made daily at a large number of selected stations in the British Islands, also in and around the Atlantic and at places on the European continental coasts. By combining these observations in synchronous charts and otherwise, it was discovered that, irregular as changes of wind and weather seem to our usual apprehension, there is really so much uniformity and similarity of character in successive variations that, by means of a comparatively small number of observations made daily at a few selected stations sufficiently far apart, and a central station to which meteorological telegrams are sent from the outlying stations, it was seen that distinct intimation of marked changes of weather and warning of dangerous storms might be given at the centre, and thence to all other points of any telegraphic combination." (p 11.)

A few pages previously, in the incongruous way that official reports are usually drawn up and allowed to pass, it states that "By continued and consecutive series of charts, several hundred in number, constructed on the simultaneous or synchronous principle, an insight into the laws of our atmosphere—into meteorological dynamics (distinct from statical results previously obtained at observatories and elsewhere), has been gained, which has enabled us to know what weather will prevail during the next two or three days, and, as a corollary, when a storm may occur. These seem to be satisfactory and rewarding results." (p. 4.)

Admiral Fitzroy reproduced these statements, with more or less alteration, in his work entitled "The Weather Book," published in 1863, but it is important to note (at p. 34) he adds to the discoveries made by means of the charts, "real proof of areas of depression" of barometric pressure. At p. 107 (we are quoting from the first edition) we read: "Soon after a few of the earlier synoptic charts were partly filled, it became apparent that while there are various currents, sweeps, or circuits in any given area of our temperate zone, intermixed and incessantly moving, the whole body of them (as a connected group), the entire mass of the atmosphere in our latitude, has a constant, a perennial movement towards the east, averaging about five miles an hour." It is remarkable that he calls this a "key to the subject" of foretelling common alternations or changes of wind and weather! This law, if it be indeed fact, is referred to again and again in this most discursive book; but we fail to find that any proof of its reality has ever been made apparent, and it seems to us that proof is eminently required as to the lateral motion towards the east of all winds coming from any of the points of the compass having E to them. Is it not to be regretted that no special report has ever been made of this elaborate investigation? The extensive gratuitous co-operation given to the work, and the great expense it must have been to the public, ought to have rendered it an imperative duty of the office to have reported fully what had been done, and what results had been obtained. Admiral Fitzroy appears to have regarded the experiment as made to gain experience for himself individually, and no doubt he turned it to good account when he inaugurated his system of telegraphing daily weather, grafting on it his method of forewarnings for storms, and his attempt at forecasting weather. Doubtless the public even now benefit by it, in the present practice of the office in giving daily reports of weather and intelligence of atmospheric dis turbances. It would be curious to know whether this long series of charts bears out

the law of wind direction and force in relation to barometric differences of pressure. If so it is certainly very unaccountable that he should have stated that "Neither isobarometric curves nor any kind of wave or crest lines seem to show directions of wind"—Report 1864 (p. 23)—and that "the highest barometer and lowest temperature are about midway in the polar current, the lowest or least tension with the warmest air being near the middle of each tropical current." (p 22.) A corroboration this of Cowper's lines—

Reasoning at every step he treads,
Man yet mistakes his way.

These statements are now well known to be incorrect, and the inference is that his charts, somehow or other, failed to interpret the law truly. If this is the case, then there were either some radical defects in the method of charting, or the materials used were bad. In either case, it would be instructive to know the cause of failure. It is as important to eschew doubtful data as it is to avoid defective modes of investigation.

Omission to do what is necessary
Leaves a commission blank to danger.

A similar work has been taken up by M. Le Verrier, Director of the Imperial French Observatory, but how differently has he proceeded. The charts are published periodically as atlases, and show simultaneous weather states over the whole North Atlantic. As specimens of lithography they are really excellent. The plan of execution is simple and readily understood. However, we have heard objection to the manner of dealing with the data in reference to time. It appears that the charts are not strictly synoptic, the data not being reduced to exact instants of time by allowing for differences of longitude. This, in our opinion, must vitiate the value of such charts. We are bound, however, to state that we have only been able to obtain a cursory glance at these atlases, and they require to be examined and compared with great care in order to arrive at any generalisations that they may afford. We trust that some English meteorologist who has access to them will give them a special study, and communicate to the public his inductions from them. The field must be a fruitful one if it only receive better cultivation. We owe much of our information respecting the laws of weather, as at present understood, to the labours of Fitzroy, and it seems apparent that he gained his insight into these laws from the synoptic charts which he constructed in 1858, from which originated his telegraphic weather scheme, commenced practically in 1860.

THE EDMUNDS CASE.

THE proceedings instituted against Mr. Leonard Edmunds by the Crown for certain moneys claimed by it, have been so frequently before the public that it is unnecessary to enter again into their details. We may briefly mention that after the Chancery suit had dragged its weary length through a number of hearings, it was referred to arbitration. The arbitrators set diligently to work to bring the question of Mr. Edmunds' liability to an issue, and after several sittings they took time to consider their award, which they have now made. To the arbitrators was referred not only the Crown's claim against Mr. Edmunds, but, on the other side of the question, they were to make any recommendation to her Majesty's Government on account of any substantive claim of Mr. Edmunds against the Crown, or on account of any claim against the Crown in consequence of the reports of Messrs. Greenwood and Hindmarsh. The arbitrators sat eleven days in public, taking evidence and hearing counsel in the case. In their award, which has just been made, they find that there is still due from Mr. Edmunds to the Crown, £7,142 13s. It may be added that this sum of £7,142 13s. is independent of and in addition to the sum of £7,872 5s. 6d. refunded by Mr. Edmunds in September, 1864, making in the whole £15,014 18s. 6d. We append a verbatim copy of the finding of the arbitrators, which is as follows:—

We award and adjudge that, on the taking and adjusting of the accounts, in the said order referred to, there is due by the said Leonard Edmunds the sum of £8,544 18s., including the sum of £3,033 16s., due from him on account of fees and emoluments received by him in respect to the parchments account.

And we award and adjudge that there are, having regard to all the circumstances, moral grounds for recommending the Government to relieve the said Leonard Edmunds from a part of the moneys due from him on account of the said fees and emoluments received by him in respect of the said parchments account; that is to say, to the extent of £1,402 5s., and we recommend accordingly.

And we award and direct that the said Leonard Edmunds do pay to her Majesty the sum of £7,142 13s., being the amount remaining due from the said Leonard Edmunds upon the taking and adjusting of the said accounts, after deducting the sum of £1,402 5s. And as to the said substantive claims brought before us by the said Leonard Edmunds against the Crown, having regard to all the circumstances of the case, we make no recommendation to the Government in relation to any of such claims.

And as to the said suit in Chancery, we award, adjudge, and decree that neither party has any claim against the other in respect of any matters in question in the said suit not concluded by the said decree or by this award.

And we further award and adjudge that each party do pay his own costs, as well of the said Chancery suit as of the reference; and that the Crown and the said Leonard Edmunds do each pay a moiety of the costs of the award.

In witness whereof we have hereunto set our hands this 27th day of November, in the year of our Lord 1869.

(Signed) George Denman.
Charles E. Pollock.

THE THEORY OF STRAINS.

WERE any proof required that our knowledge on the subject of the strength of materials was dependent upon somewhat antiquated sources of information, it is furnished by the opening paragraph of Mr. Stoney's new volume.* In it he is compelled to refer to experiments conducted exactly fifty years ago in order to commence his remarks on compressive strains. Anyone who is well acquainted with the history of the experiments that have been made with reference to the resistance of various materials to strains of different kinds must be aware of the spasmodic nature of their occurrence. The series of valuable empirical results obtained during the designing and execution of the Menai Bridge was never systematically followed up. No sooner was that magnificent work completed than no further thought was bestowed upon the means which had alone rendered the design successful. We do not mean to assert that no experiments have been made since that time which are not, or rather which might not be, of value to the profession, but they have been conducted generally by private parties for the sole purpose of self-satisfaction. That object once accomplished no pains are taken to render the results of public utility, nor even during the experiments to elicit any information but what may be of interest to the parties themselves concerned. So far, therefore, as the professional man is in question or the hope of improving our professional knowledge on the subject, such experiments might just as well not be undertaken. Moreover, supposing that the various experiments that have been undertaken from time to time by private parties had been made public and conclusions deduced from them in the shape of rules and calculations, yet the same confidence could not be put in them as in those drawn from a thoroughly organised series carried on under the same conditions of time, place, and superintendence. The mere labour of compiling the results of a large number of heterogeneous experiments, of reconciling the discrepancies, and adjusting the differences would be exceedingly great, and the uncertainty of their accuracy would be still greater. Engineers would feel no confidence in them and their end would thus be completely frustrated. With these preliminary observations we turn to a consideration of the contents of the volume before us.

Any author who treats of compressive strain must, similarly to Mr. Stoney, draw nearly all his information from the researches of the late Mr. Eaton Hodgkinson and those who were associated with him in the elaborate series of experiments he undertook. So also to a certain extent with the subject of extension or tensile strain, especially so far as it affects cast iron. Practically the tensile strength of cast iron is of very little importance. Bearing in mind that it is not safe to strain cast iron in actual working beyond 1·25 tons per square inch of sectional area, it is clear that its duties in this capacity will always be of a very limited character in any design which is in accordance with the correct principles of construction. It is well known that in wrought iron the shearing strength and the tensile are practically the same. But the same identity does not exist in steel with reference to these two strains, since the shearing strength of rivet steel is only three-fourths of its tensile strength. The important point in connection with this difference is that it will very materially influence the arrangement of jointing and joining different pieces of steel. This will have to be very carefully considered in disposing the joints in the flanges of a steel girder or other structure of that material. So soon as the spans of bridges attained any degree of magnitude it became imperative to provide some means of permitting the alterations in the dimensions to take place unchecked. Arches and the cables of suspension bridges require no special provision of this kind. The former simply rise at the crown, and the latter drop at the lowest point of their catenary. Horizontal girders expand and contract in proportion to their length at their extremities, and it is clear that unless they can do this freely they will alternately push outwards and pull inwards the abutments upon which they rest. For small spans Mr. Stoney mentions that sliding surfaces may be used, and rollers for larger spans. There is only one point to be attended to in this matter, and that is, whether sliding surfaces or rollers be used, see that they act. It is worth bearing in mind that a change of temperature of 15deg. Centigrade in cast iron is equivalent to a strain of one ton per square inch, and that an alteration of only 8deg. is sufficient to cause the same result in wrought iron. Tubular girders and all those pertaining to the solid-sided type of construction are much more affected by alternations of temperature than the open or lattice web principle.

Our author, in his chapter on "Flanges," points out the manifest superiority, as regards stiffness, possessed by a number or pile of plates over the cellular system, thereby confirming the often expressed opinion of Mr. Hodgkinson that thick plates are the best protection against buckling. The argument that has been urged against the uniting together of a number of plates is invalid. There is no difficulty in getting the riveting well done, and rivets have been used eight inches in length, and the holes have been subsequently found perfectly filled up when the plate was sheared across to examine the state of the work. The minimum thickness that should be employed for the side of

* "The Theory of Strains in Girders and similar structures; with observations on the application of theory to practice, and tables of the strength and other properties of materials." By Bindon B. Stoney, B.A., Member of the Institution of Civil Engineers, and engineer to the Dublin Port and Docks Board. In two volumes, with numerous illustrations, engraved on wood by Oldham. Vol. 2. London: Longmans, Green, and Co. 1869.

a plate girder is put by Mr. Stoney at one quarter of an inch, but it is open to question whether this is not fining down the material too much. Many engineers will not use a plate less than three-eighths thick, and we are disposed to consider such a resolution a very wise one, although the lesser thickness is defended upon the ground that, by the aid of stiffening irons, sufficient strength can be imparted to it. Against this defence, which is valid to a certain extent, must be set the fact that no plate is stronger than its weakest part, and that a distinction must be drawn between increasing the whole sectional area, and consequently the strength of the whole web or side, and augmenting merely the strength of certain portions of it.

If there is one chapter more than another in the book that we should especially recommend to the notice and careful study of our readers, it is that on the "Working Load." The remarks are not confined to iron structures, but embrace those of timber, brickwork, and masonry. Considerable diversity of opinion has always prevailed among engineers from the earliest times respecting the ratio between the ultimate and the working strain of any material. At the present day the question is still undecided. As an example, the allowance of weight to be made per square foot, as the maximum that is to be provided for in designs for public road and street bridges, is variously estimated, and ranges from 70lb. to 147lb. per square foot. Our author recommends 100lb. as a safe limit, but a more convenient one for calculation and remembrance would be 112lb., which would give twenty square feet to the ton. An appendix and several plates are attached to the volume, the former containing a description of the principal types of bridge construction recognised by the profession, and the latter serving as illustrations to the text. Both Mr. Stoney's volumes should be in the possession of everyone who lays any claim to scientific designing and who may be desirous of possessing the most recent information with respect to so important a branch of knowledge as the theory of strains and the strength of materials.

TELEGRAPHIC NOTES.

WE are glad to be able to announce that the "Great Eastern," which carries the Bombay and Suez section of the British-Indian Submarine Cable, arrived at St. Vincent, Cape de Verds, on November 19, after a successful passage from Portland of thirteen days. Captain Halpin reports that the big ship behaved remarkably well during the voyage, and that the weather had been fine and the sea smooth the whole of the time. In consequence of an almost entire absence of wind no sails could be used, and the average steaming power was 7¾ knots per hour all the passage to St. Vincent. "Everything," says Captain Halpin, "has gone on most satisfactorily since we left; all hands are well, and if the water keeps smooth I expect to leave here on the 25th for the Cape of Good Hope. The weather here is unusually hot, and I am wishing myself at sea again." The passage from Portland to the Cape de Verds was unattended by a single hitch. After taking in supplies at the Cape of Good Hope the "Great Eastern" will proceed direct to Bombay, and commence at once to lay down the cable—a portion of which is now *en route* by the Suez Canal to the Red Sea.

We understand that the arrangements for the taking over of the telegraph system by the Government are now not likely to be completed before the end of January next. Meanwhile, it is believed that the negotiations between the Government and the companies with regard to the time and mode of payment of the compensation money have not yet been concluded, although an early announcement is expected. With regard to the financial aspect of the question, it appears that the total sum to be raised will probably be about £7,000,000, taking into account the expenses in connection with the reconstruction and enlargement of the general business. But the portion to meet the awards to the companies is limited to £5,715,048, and an impression is entertained that the large balances that will accumulate in the Exchequer in January from the new arrangements regarding the income and assessed taxes will, with or without some assistance from the Bank of England, prove sufficient for that purpose. Another account which has reached us says that the Chancellor of the Exchequer has arranged his resources for the purchase of the telegraphs on the 1st proximo. He will, it is alleged, borrow from the India Council, also from the Post-Office and other Savings Banks, and also from the Consolidated Fund. Should he require a little further assistance he may obtain an advance from the Bank on deficiency bills.

The Russian Government has granted a concession of thirty years to M. Titgen, Councillor of State to the King of Denmark, M. Erickson, a merchant, and M. Pallisen, consul-general for that country at St. Petersburg, for the establishment of submarine telegraphic lines between Asiatic Russia and Osaka, Yokohama, or Nangasaki, in Japan; and Shanghai, Fou-djaon, and Hong Kong in China. The company thus formed will ask for the authorisation of the Chinese and Japanese Governments, and the Russian executive will lend its good offices in the matter. The concessionaires bind themselves to attach this system of telegraphy to a station and telegraphic line of the state in Russia in Asia.

Captain R. B. Oldfield, of the Royal Navy, an experienced officer, has been granted leave by the Admiralty, and has proceeded, on behalf of the Telegraph Construction and Maintenance Company, to Siam and the Malay Peninsula for the purpose of exploring certain routes by which that company proposes to establish a telegraph communication from Burmah, the Tenasserim Provinces, and Siam with Penang, so as to throw the traffic upon the British Indian Extension Company's cable, which will be laid next year between the Straits of Malacca and Ceylon.

We learn that a company is in course of formation, to be called the Anglo-Australian and China Telegraph Company. They propose to establish a submarine telegraph between Calcutta and the Australian colonies, with intermediate stations at Penang, Malacca, Singapore, Batavia, and the Dutch settlement at Macassar, the cable terminating in Queensland, at the head of Gulf Carpentaria, to which point the telegraph system of Australia will be completed in 1870.

It is stated that several new submarine cable companies are coming out, and that they promise to increase during the next two or three months. A variety of mining enterprises, some of them American and Australian, are in course of organisation, so that the much-needed activity in industrial enterprise is anticipated.

In order to effect a direct communication between the French Atlantic Telegraph Cable and London, a submarine cable between Salcombe and Brest is now being laid. The shore end was on last Friday landed at Salcombe, Devon.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

TO DYE MACINTOSHES OR INDIA-RUBBER CLOTH.

THE india-rubber garments which still bear, and will perpetuate, the name of Macintosh, have not, it must be admitted, a pleasing appearance. Putting aside all objections on the score of fit and elegance in the coats, and granting that the ladies' capes do not leave much to be desired in their shape, there is still a sad want of variety of colour. We have merely a choice between funereal blackness and a staring dirty white, which is even more unpleasing. For this, unfortunately, there is every excuse. The mineral ingredients mixed with the rubber to give colour and substance to it are necessarily subject to the action of the sulphur employed to effect the vulcanisation, and although it would not be impossible to produce a few dull shades of colour even under these circumstances, manufacturers apparently do not care, or are not sufficiently instructed, to produce the necessary compounds. A mineral colour mixed with the rubber would have the recommendation of permanency; but, so far as we can speculate without making experiments, the shades producible would be somewhat dull. A process, however, comes to us from Germany which seems to make it possible that the brightest of the aniline colours may be applied to rubber garments. Necessarily, the material being quite impermeable, the first step is to get a surface to fix the colour—and this is done by coating the cloth with albumen, just as is done in the case of cotton, which alone will not take the aniline dyes. For this purpose, if we take the case of a zephyr cloth—that is, the rubber compound spread upon silk—the surface of the rubber should be brushed over with albumen, which must be allowed to dry thoroughly. The cloth may then be passed through the dyeing bath, and the colour would be taken both by the silk lining and the albumenised rubber. A reversible garment would thus be obtained, exhibiting pretty much the same shade of colour on both sides, and with aniline dyes a sufficient variety of shades could be procured to make ladies' cloaks, at all events, ornamental as well as useful. When the Lord Mayor or Royalty appears in public in wet weather every spectator sympathises with the flunkies, whose gorgeous liveries are concealed under dirty-drab macintoshes. Henceforward, thanks to this happy suggestion of a German chemist, the royal footmen may turn out in the worst weather in bright red, and those of the Lord Mayor (if such be his choice) in the clearest blue. We may commend this process to the notice of manufacturers, and also of dyers, and shall soon hope to see some applications of it.

INSTITUTION OF CIVIL ENGINEERS.

AT the meeting of this society on the 7th ins. Mr. C. H. Gregory, President, in the chair, the first ballot of the session 1869-70 was taken, when the following forty-seven candidates were duly elected, including six Members, viz.:—Mr. J. W. Blackburne, Oldham; Mr. F. Charlton, Northumberland; Mr. George Gilroy, Wigan; Mr. John Knowles, Pendlebury; Mr. Francis Mathew, Bombay and Baroda Railway; and Mr. H. F. Whyte, A.B., Bombay and Baroda Railway. Forty-one gentlemen were elected Associates, viz.:—Mr. J. Abernethy, jun., Alexandra Docks, Newport, Mon.; Mr. E. Armitage, Westminster; Mr. G. F. Armstrong, M.A., Norfolk-street; Mr. J. H. Babington, East Indian Railway; Mr. J. Battersby, East Indian Railway; Mr. G. Blaxland, jun., Cannon-street; Mr. A. B. Bradbury, Madras Irrigation Works; Major Frederic Brine, R.E., Simla; Mr. E. J. Bristow, Copthall-buildings; Mr. J. B. Cooper, Stafford Railway; Mr. J. Dixon, Laurence Pountney-hill; Mr. T. J. Ellis, Westminster; Mr. A. Field, Widnes; Mr. C. Flood, Falmouth Harbour Works; Mr. J. G. Gamble, B.A., Albert Dock, Hull; Mr. L. A. Golla, Extension Works, Chatham; Mr. F. B. Henslowe, Oudh; Mr. A. S. Hewitt, New York; Mr. W. Innes, Lieut. R.E.; Mr. E. Lawrence, B.A., Lambeth; Mr. A. Leslie, Edinburgh; Mr. F. Livesey, Gas Works, North Shields; Mr. W. H. Long, Union Club; Mr. J. W. Miers, late of Rio de Janeiro; Mr. J. W. Pease, M.P.; Major C. Pollard, R.E., Central Provinces, India; Mr. J. Prestwich, F.R.S., Shoreham; Mr. C. Prime, Ceylon; Mr. W. E. Rich, Southwark; Mr. W. I. Roach, Trinidad; Mr. W. R. Scanlan, Walsall; Mr. H. A. Taylor, Westminster; Mr. C. Thwaites, Bombay; Mr. H. C. A. Timmins, West Malling; Mr. R. H. Twigg; Mr. R. Vigors, Old Jewry; Mr. H. C. E. Wenden, Great Indian Peninsula Railway; Mr. C. Wilks, Melbourne; Mr. A. F. Wilson, Brazil; Mr. T. Wrightson, Stockton-on-Tees; and Mr. A. F. Yarrow, Poplar.

It was also announced that the Council had recently admitted the following candidates as students of the institution, viz.:—Messrs. E. A. Abbatt, J. V. Aguilar, R. D. Baillie, E. Bainbridge, G. H. T. Beamish, F. E. Burke, J. Cartmell, G. H. R. Deverell, G. W. Fuller, R. N. Hodges, R. S. Hodgson, H. F. Joel, C. U. King, R. Lathbury, S. Lambert, P. W. Meik, W. I. Noad, G. W. Randolph, G. Remington, jun., J. C. Searle, J. Strachan, J. J. Talman, A. G. Tengbergen, C. Thomson, F. E. Townshend, A. W. Tyrrell, G. W. Usill, D. Wallace, J. S. Webb, A. Wheatstone, and J. M. Wrench.

IT is said that in view of the opening of the Suez Canal, the Russian Navigation and Trading Company is about to establish, immediately, a through service of steamers between Odessa and Bombay.

STEAM FIRE ENGINE FOR LITTLEPORT.

A NEW steam engine has been recently supplied to the parish of Littleport, near Ely. This engine has been specially constructed for the Fen district, for it is well known that the roads in that part of the country are totally unlike our town roads, being very marshy, and covered with deep ruts. The practicability of transporting such a machine at a rapid rate was very much doubted, but owing to the visit of Mr. J. Compton Merryweather, one of the firm of the manufacturers of the engine, previous to its delivery, all such doubts were removed, as special arrangements were made in the construction of the wheels and carriage work to obviate this. The engine supplied is similar to those made by Messrs. Merryweather and Sons for her Majesty's Government, the Royal dockyards, various country towns, and one of this class was exhibited at the Smithfield Club Cattle Show. The Littleport engine was worked on its arrival in the town. Steam was raised to a working pressure of 100lb. in 10½ minutes, the coal used being very inferior and the wood damp. Half a mile of delivery hose was connected to the delivery of the engine, and the result was that an inch jet was discharged 65ft. from the nozzle, which would reach far above the highest house in the town. The trials were superintended by Mr. J. C. Merryweather and Mr. T. Stancliff, the manager to Messrs. Merryweather and Sons, and the brigade was drilled for some hours, during which different experiments were made much to the satisfaction of the overseers, parishioners, and various gentlemen who had come from Ely and the neighbouring towns to witness them.

SOCIETY OF ENGINEERS.

AT the last ordinary meeting of the Society of Engineers, held on Monday, the 6th inst., Mr. F. W. Bryant, President, in the chair, the adjourned discussion took place on Mr. Charles J. Light's paper on the need of further experiments on the strength of materials. After this discussion a paper was read on apparatus for measuring the velocity of ships, by Mr. Vaughan Pendred. The author pointed out the various attempts that had been made to produce instruments for this purpose, and described a few of the most practical, including those of Massey and others. He then proceeded to explain in detail, and by the aid of models and drawings, the beautiful invention of the Rev. Edward Lyon Berthon for measuring the speed of ships. It consists simply of a tube dipping a few inches below the bottom of the vessel and communicating with recording apparatus on deck or in a cabin. The tube is closed at the bottom, but has a hole in the side by which the water is admitted. Pressure is communicated to a column of mercury, which registers the speed of the ship. We purpose giving this paper *in extenso*, and therefore reserve our detailed description till then. An interesting discussion followed the reading of this paper, in which Admiral Halsted, the Rev. Mr. Berthon, and other gentlemen interested in the question took part. At the close of the discussion —which was adjourned to the 20th inst.— the following candidates were balloted for and duly elected as Members:—Mr. George Farren, C.E., Clynnog, Carnarvon; and Mr. Alfred Hope, gas engineer, The Hollies, Hastings. As a foreign member Mr. George Thomas Light, Adelaide, South Australia; and as an Associate Mr. Frederick Williams, Abingdon-street, Westminster.

STRENGTH OF THE ROYAL NAVY.

AN Admiralty return shows that the number of first-class boys in Her Majesty's service was 4,335 on April 1, 1866, 3,984 on that day in 1867, 4,621 in 1868, 4,738 in 1869; and of second-class boys (nearly all in training ships) 2,690, 3,174, 3,025, and 2,999 at the respective four periods. The number of boys entered for the first time on board Her Majesty's ships was 2,225 in the financial year 1865-66, 3,123 in 1866-67, 3,077 in 1867-68, 2,351 in 1868-69. The number of *bona fide* seamen who were rated from boys was 1,470, 2,399, 2,078, and 1,802 in the four years respectively. The number of *bona fide* seamen (exclusive of pensioners on the books of Her Majesty's ships and coastguard men on shore) on April 1 was 19,883 in 1866, 19,624 in 1867, 19,456 in 1868, 18,915 in 1869; and the number of coastguard fleet men on shore 3,745, 3,892, 3,980, and 3,795 respectively. The number of *bona fide* seamen who entered the Royal Navy from the shore, merchant, or other service for the first time in the year 1865-66 was 485; in 1866-67, 409; in 1867-68, 445; in 1868-69, 214; and the numbers who re-entered were 1,136, 920, 844, and 775 respectively in those four years. The number of *bona fide* seamen who left the service, being paid off to the shore, or discharged as "objectionable," &c., was 2,362 in 1865-66, 2,141 in 1866-67, 1,886 in 1867-68, 2,374 in 1868-69; and the number who left from other causes—death, invaliding, desertion, discharges with disgrace, by purchase, or on pension—2,007, 1,936, 1,612, 1,528 respectively. The number of boys who left the service from all causes was 430, 634, 550, and 552 respectively in the four years.

ANGLO-FRENCH COMMUNICATION.*

By Mr. Zerah Colburn.

FROM the period of the Roman invasion down to the present day, the English Channel has never been crossed otherwise than upon its own surface—unless the late Mr. Green's aerial voyage be an exception. Neither Julius Cæsar, however, nor William of Normandy lived in a railway age, and but for the miseries of sea sickness, they doubtless preferred the sail to the best roads of their respective times. But since railways have become the recognised means of communication on land, the question has been pressed, and of late very urgently pressed, whether they may not be also made available for communication—not exactly upon the water, although there is a floating railway across the Upper Rhine—but over or beneath the water, and especially over or under the comparatively narrow and shallow strait which separates our island from the continent. There are *soi-disant* patriots, it is true, who would on no account witness the loss of our absolutely insular position, patriots to whom England is a castle, and the stormy Channel its moat, and who would not have so much as a drawbridge thrown across that moat, or a hidden way mined beneath it. Such considerations are, however, apart from the present purpose, which is, not to inquire into the international policy or financial expediency of solving this great intercostal problem, whether by a bridge, a ferry, or a tunnel, but to examine, very briefly, the engineering and constructive aspects of these proposed works. It is probable that the greater the apparent impracticability of either or all of these schemes, the greater the general interest they attract, and perhaps the same interest may be said to exist also among the members of the engineering profession.

The question of bridging the Channel has been mooted, and at least one scheme has attained some degree of public prominence. The designer's first proposal was to jump the Channel at a single leap, but whether out of his regard, as has been asserted, for the wishes of the Emperor, or from a willingness to conform to certain immutable laws of nature which render such a plan impossible, he subsequently modified his design so as to include ten spans, and it has been since heard that he is willing to extend their number and reduce their width to twenty, of one mile each. Whether even such a superstructure, to say nothing of the piers in a maximum depth of 200ft. of water, and rising more than 200ft. above its surface, would or would not be practicable, is a question which may be safely left to those really competent to deal with it, and of these the designer himself can hardly be considered to be one.

Of the entire practicability and great advantage of a Channel ferry there can be no doubt whatever, whether it be established between Dover and Calais, or between Dover and Audresselles. It is quite practicable to ship and unship passenger and goods trains bodily, and thus to run them through, both ways, between London and Paris. Boats suited for this purpose, and harbours capable of receiving them, could be constructed within a few years at a cost much less than that of any tunnel, whether laid on the bed of the Channel, or carried through the chalk at any depth below it. Such boats would be in as striking contrast to the existing Channel service as that afforded by our finest hotels on the one hand, and the most uncomfortable lodging-houses on the other; or, if another illustration be needed, the most luxurious express saloon carriage and the most cheerless third-class conveyance to be found on any railway in the kingdom. But any boat service whatever, however excellent it may be, has its necessary drawbacks. No ferry-boat, even if nearly as large as the 'Great Eastern" herself, could wholly prevent the possibility of sea sickness, that unspeakable horror of so large a proportion of all landsmen, of whatever nationality. The time occupied in shipping and unshipping trains, however expeditiously the work was performed, would be considerable, and however high the speed of the boat as a boat, it could not exceed one-half that easily attainable by a railway train. As to the relative safety of a boat service and a train service, it is not now necessary to inquire, although something, if not, indeed, much, might be urged with reference to collisions in fogs or storms. But the chief objection to boats would be their high cost of working and maintenance. As it would not answer the convenience of the public to detain a boat until two, three, or more trains had arrived at either port, a boat would be required for every train, and its working charges might, therefore, be fairly compared with those of a single train. The consumption of coal alone, with boats of the proposed size and speed, would be from fifteen to twenty times as much as that for the train if run across by itself. The repairs and depreciation of the boats would be very much greater, per pound of their value, than that of the train, and the boats themselves could hardly cost less than £100,000 each, while the train carried, including the cost of engine and tender not carried, would not represent a cost much above £6,000 or £8,000. The wages of captain, engineers, firemen, stewards, porters, and crew would obviously be far beyond those of the three or four men working the train by itself, and these, and all other working charges, would be divided, mile for mile, upon a very much less number of miles per annum than the number made by the train if run by itself. There would not, of course, be any permanent way charges with which to debit the boat, running on nature's own highway, but as to capital charges, the interest upon the cost of the harbour works alone would probably be equal to that upon a railway costing £100,000 per mile. It is morally certain that a large Channel ferry, with a full complement of steamers, could be maintained only by a very decided advance in the fares, whether between the opposite coasts alone, or between London and Paris. Assuming that even as many as 100 passengers were taken across in a single train, the capital charges and working expenses would probably amount to £20 per trip, assuming the boat to make 1,000 trips of 20 miles each per annum, and thus the charge per passenger would be 4s. for 20 miles, or nearly 3d. per mile. The carriage of goods, specie, &c., would lessen this rate, but it is as likely also that the average number of passengers per trip would be very much less than 100. Nor is it at all certain that each boat could make four trips daily for 250 days in the year. None of these reasons, however, patent as they are to the observation of all, are conclusive against the Channel ferry. On the contrary, the ferry is the only means of maintaining comparatively expeditious and comfortable communication, of which the absolute practicability is beyond all question, while it could be got to work within probably two, three, or at most four years, and at a cost, including harbours, of probably little more than £2,500,000.

That branch of the question which possesses real interest—surpassing interest of uncertainty —at least for the engineer, is that relating to a subaqueous way across the bottom of the Channel, or a regularly excavated tunnel a hundred yards or so deeper down in the grey chalk or clay itself. It is, perhaps, the certainty (the question of first cost being for the moment dismissed) that a tunnel, once made, would prove the very best of all means of crossing the Channel, and the qualified uncertainty whether such a tunnel is even practicable at all, that give to the tunnel question its great, its even seductive interest to engineers. It need hardly be said that tunnels under water, or rather through the earth beneath the water, are anything but new or unusual. For very many years the tin miners of Botallack, in Cornwall, have driven their headings to a good distance beneath the very bed of the Atlantic itself. Just sixty years ago Trevithick nearly completed a tunnel beneath the Thames between Wapping and Rotherhithe, and but for imprudently making a bore hole from the roof through to the river bed, this tunnel would no doubt have been successfully opened. Ralph Dodd had made the same attempt before. Brunel's world-famed tunnel requires no remark, and it will be but a few weeks before Mr. Barlow's tubular subway will be carried through from the Middlesex to the Surrey shore. The longest tunnel under water is that, two miles in length, of the waterworks at Chicago, United

* Read before the Society of Arts.

States. This tunnel, although but 5ft. in diameter, is carried out to where the water above it is 40ft. deep, the tunnel itself being 30ft. below the bed of Lake Michigan. There is also a tunnel under the Chicago River at the same place. At home we have no less than three schemes for tunnelling beneath the Mersey, at Liverpool, and three for tunnelling beneath the Severn below Gloucester, and in both instances one of the three schemes will in all probability be yet carried out. Provided only the bed of the channel or river beneath which the tunnel is to be made is nearly or quite impervious, under-water tunnelling is no more difficult than underground tunnelling. And there may be shafts, even, to under-water tunnels, just as the Chicago Lake tunnel has its shaft through which the water supply is taken, but which was employed, during construction, for the ordinary purpose of giving a second working face and for discharging the excavated materials,—this shaft being two miles from shore. This tunnel was carried through a continuous bed of tenacious clay, as impervious to water as marble itself. But in the proposed Channel tunnel, to be made at a depth of about 500ft. beneath the surface of the sea, it is needless to remark that a single fissure in the chalk, however narrow, would be rapidly widened by the tremendous abrasion of water under the great pressure of 200lb. per square inch; so rapidly that probably no efforts to clear the workings could be expected to succeed. A fault of great vertical magnitude is well known to divide the chalk beneath London, although neither the precise line of this fault, to within a few yards, nor the width, if any, to which the chalk bed is separated at the point, are known. Whatever may be inferred from the geological analogies of the chalk on the English and French coasts, it cannot for a moment be positively asserted that a fault beneath the middle of the Channel does not exist, nor, it is as well to add, can it be asserted, on the contrary, that a fault does exist. The question can only be settled by a trial heading or driftway, and, whatever the real danger, there are plenty of navvies and miners who, knowing no fear, are ready and willing to face it when the eminent engineer, whose name is connected with the proposed undertaking, finds himself in a position to give the word. Let two headings, each eleven miles long, once be carried out to meet each other beneath mid-channel, and the success of the tunnel, so far as its completion is concerned, is assured. It would be a matter of long and tedious boring and blasting, and one in which uncertain millions would certainly be swallowed up, but it would all come right at last, supposing, of course, that by previous experiments upon that thirsty material, chalk, no excessive infiltration of water under a maximum pressure of 200lb. per square inch was found to take place, and there would be 24 acres of roof of each heading of 9ft. in width, the ceiling, if it may be so termed, of each heading of 9ft. width amounting to rather more than an acre per mile.

There are two distinct schemes for a tunnel beneath the bed of the Channel, but the same general certainties and uncertainties apply to both. It is only from geological inferences that either can claim superiority over the other. It would require space far beyond the limits of the present paper to deal even with the geological aspect of the question alone. It is but right, however, to remark that geological evidence, as far as it goes —for the materials at command are scanty—points strongly to the probability of the complete continuity and homogeneity of the chalk which forms the upper beds of the broad and shallow submarine valley separating our island from the Continent.

Bridging, steam-ferrying, and tunnelling fall within the ordinary range of engineering. But no engineer has yet attempted to lay down a railway upon the bottom of the sea itself—a railway, the passengers of which, like the Israelites of old, should go over, or, rather, under, dryshod, not only with a dense wall of water on either side, but with 80 fathoms or so over their heads. It is not the purpose here to enter at length on the relative advantages and disadvantages of subaqueous ways—a term employed merely to distinguish railways on the Channel bed from those in tunnels beneath it, as compared with railways deep down in the chalk. As, however, the remainder of the present paper will be chiefly devoted to the examination of the mode of constructing subaqueous ways, it will be but fair to enumerate the objections which may be urged against them. They are these:

Beyond some amount of uncertainty necessarily attaching to the laying of such ways, they might possibly be injured by the dragging anchors of vessels, or broken in two by the sinking wreck of an iron steamer dropping upon them. They might, possibly, suffer at the shore ends, where they rose to within the action of the waves in heavy storms. They could always be destroyed wantonly, and with little fear of detection, by sinking a charge of gunpowder upon them, at any portion of their length, and then firing the charge, at a safe distance, by electric wires. It might be urged, too, that a large tube, especially where it rose like a huge groyne, in shore, might cause injurious disturbances of the Channel bed, thus affecting navigation. In any case, the tube could be started and carried forward from but one end only, as it would be out of the question to attempt to bring together, water tight, the two closed ends, or for that matter the open ends, of two tubes in mid-channel.

These appear to be the principal, if not all, of the possible objections which could be urged against subaqueous ways. The weight of these objections depends probably more upon the individual opinions of those who advance or refute them than upon any evidence capable of demonstration. As for the dragging of anchors, the various proposals (and there are several) for tubes on the bed of the Channel provide for routes well off the Varne and Colbert banks, and, it need hardly be said, miles to the westward of the Goodwins; routes upon which vessels would seldom have occasion to anchor at all, even in the worst storms. Where an anchor dragged, however, with a force of even 150 tons—the highest chain cable test of Lloyd's proving house—this could not make any definite impression upon a continuous tube weighing 8 tons or more per foot of its length, for to move at all at least a quarter of a mile of tube weighing 10,000 tons would have to be dragged upon the Channel bottom. As for breaking the tube, say 4½in. thick of cast iron with a lining of 1ft. of brickwork, the chances would appear extremely improbable. But a greater security will appear when it is considered that a cast-iron tube, say 14ft. in diameter, and having no outer flanges, presents no point upon which an anchor could bite. The chances of an iron vessel foundering exactly across the line of the tube are, to say the least, by no means numerous. In shore, that is to say in shoal water, the tube would require to be protected by strong parallel breakwaters, as much to prevent vessels grounding across it as to prevent the action of the waves upon it. The risk of possible destruction by malice—the crushing in of the crown of the tube by the explosion of gunpowder upon it in ten, twenty, or thirty fathoms of water—is a risk of which each one must form his own estimate. This mode of destruction, the consequences of which would be irreparable for all time, could most certainly be resorted to by hostile or merely malicious feeling, with almost no chance at all of detection, whereas neither a bridge, nor a tunnel deep down in the chalk, could be destroyed without some difficulty, and the certainty of the timely discovery of the attempt.

The various proposals for laying subaqueous ways upon the bed of the Channel are as distinct from the ordinary range of bridge and tunnel engineering as the making and laying of submarine cables are distinct from the construction of land telegraph lines. Of what is technically distinguished as mechanical engineering, very little is now required for the construction of an iron bridge or a tunnel in earth and rock, but the construction and laying of a subaqueous way would be, to a large extent, the work of the mechanical engineer. Such a work, upon any plan, would be one attended with many contingencies, and so far as mere ingenuity is concerned (not that the necessity for greater ingenuity is in itself an objection), the subaqueous way would incontestably require far more originality of design for its making and laying than any other mode whatever of crossing the Channel. But as engineers always rise to the occasion, it may be assumed that a plan, physically possible in the abstract, would never fall through from the want of that elaboration and improvement which are summed up in the mind of the engineer in the single word "detail."

Perhaps the first quasi-practicable plan proposed for crossing the English Channel by means of a subaqueous way was that contained in an anonymous pamphlet printed in Dublin in 1858. The author proposed to construct a 15ft. tube from Dover to Calais, extending it, foot by foot, along the bed of the Channel, from the English to the French coast. Starting from the English coast, within a structure named a "head," or a "bell," this head fitting, water-tight, around the exterior of the tube to be extended, he proposed to put together each successive length of the tube within the head, and to push the latter forward as fast as the work proceeded, the head meanwhile lying on the bed of the Channel. The calculations of resistance, and of the quantities to be employed in the tube itself, were carefully worked out, and so far as the author has tested them, these calculations were correct upon the *data* assumed. This mode of construction ensures the advantage, if it be an advantage, that each portion, whether of 10ft. or even a mile, of the length of the tube, once laid, is not again disturbed at any subsequent stage of the work. But the designer appears to have foreseen an element of possible weakness when he asserted that even were the tube rolled over in the Channel no harm could result to the passengers, and no interruption to the train service. Inasmuch as the atmospheric system was relied upon for propulsion, and the passenger compartments were to be shot through circular tubes, it might not perhaps make any difference to the passengers whether their carriages bottomed upon one part of the tube or another, but it would be interesting to know what would become of the shore ends, and, for that matter, the passengers themselves within the tube, if a few miles of the latter were really to turn over in mid-channel.

The anonymous idea of 1858 has been lately worked out in much greater detail by an eminent English engineer, whose labours have been assisted by an Austrian member of the same profession. Their plan, which has now been for some weeks before the public, provides for a cast-iron tube of 18ft. internal diameter and 4in. thickness, to be carried out in 10ft. lengths, each length being formed of six segments. The work of putting together the successive lengths of the tube is to be performed on the bottom of the Channel, within a cast-iron "bell," as it is termed, this bell or shield being 80ft. long, 18ft. in diameter, and 8in. thick. The tube is to be packed, water-tight, within this bell, and the bell itself is to be forced forward 10ft. at a time, after that length of tube has been added to the portion already laid. For forcing forward the bell four hydraulic presses, each of a maximum force of 1,000 tons, are to be employed. The details of the scheme are most ingenious; at the same time perhaps not too much so, for many a mechanical project has been ruined by too much ingenuity. It is evident that from the very confined space but a dozen men or so at most could be effectively employed at a time within the end of the tube in putting the segments together, although a much larger number, were they required merely to work the hydraulic machinery, could find room in the forward portion of the bell, and it is evident that the rate of progress of the tube would be measured by the rate of working of the dozen or so of men employed in putting the segments together, the segments being brought, when the tube was nearly completed, from a distance of (say) twenty miles through the tube itself. The segments and bolts once made ready on shore, the whole labour of putting the tube together, the whole task of maintaining its intended course, and the whole of the responsible duty of inspection as the work goes on, would be performed under water, in an artificial light and with artificial ventilation, and where, upon the occurrence of any accident causing the sudden inroad of water, all within the tube must hopelessly perish. Should the tube crack and fill with water during the process of laying it is also hopelessly lost, since no moorings are or can be attached to it during the process of laying or afterwards. That the tube might crack at some point while the shield was being advanced under a force, according to the depth and the nature of the bottom, of from 1,000 to 4,000 tons, would be nothing very improbable. And what might be the chances of leakage, with nearly 65,000 joints made in the dark, or, rather, in a very feeble light, and under water, must be left to the imagination, the joints themselves being upwards of 200 miles in aggregate length, and, taking them as 8in. wide each, presenting a total surface, for the two parts brought together, at each joint of about thirty-four acres. There is probably, nothing physically impossible in the scheme, although it would be one attended with many improbabilities of success. Nor could this plan of construction be adapted to the irregularities of the Channel bottom, upon which the gradient would occasionally require to change from level to 1 in 100, making a difference of 1½in. between the joints on the upper and lower sides of the tube, thus necessitating special castings, or involving the risk of leaking. The particular tube now under consideration would have a multitude of external flanges, and it is not improbable that it might suffer from dragging anchors. These flanges and ribs are not essential, however, to the general plan.

(To be continued.)

IMPROVED VENTILATING FAN.

BY MR. J. LLOYD.

FIG. 1.

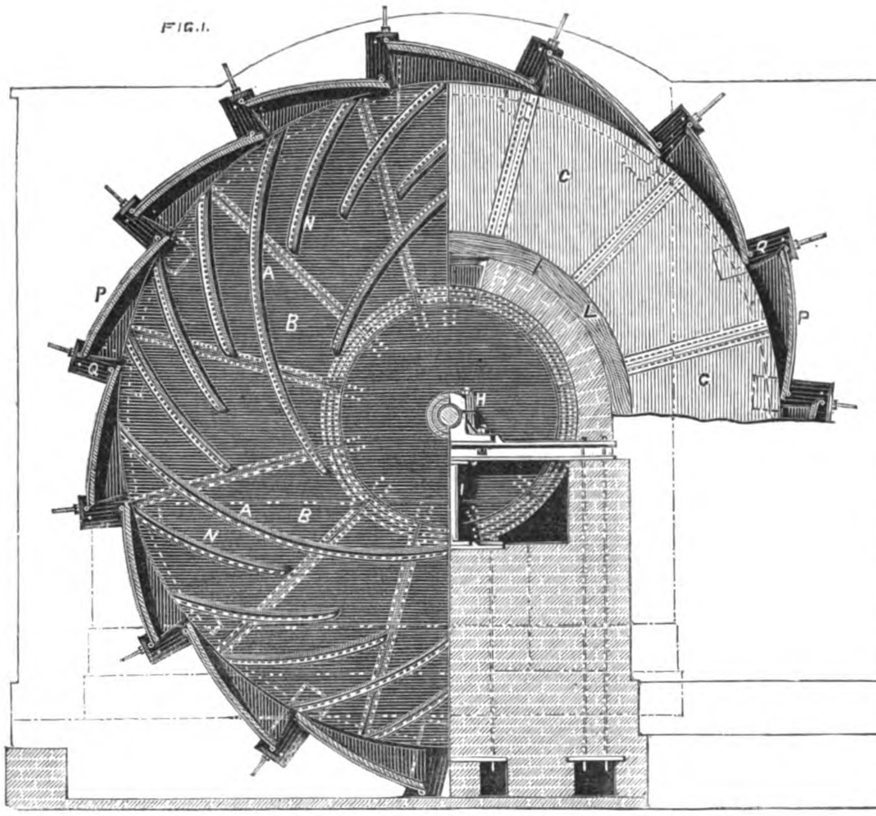


FIG. 2.

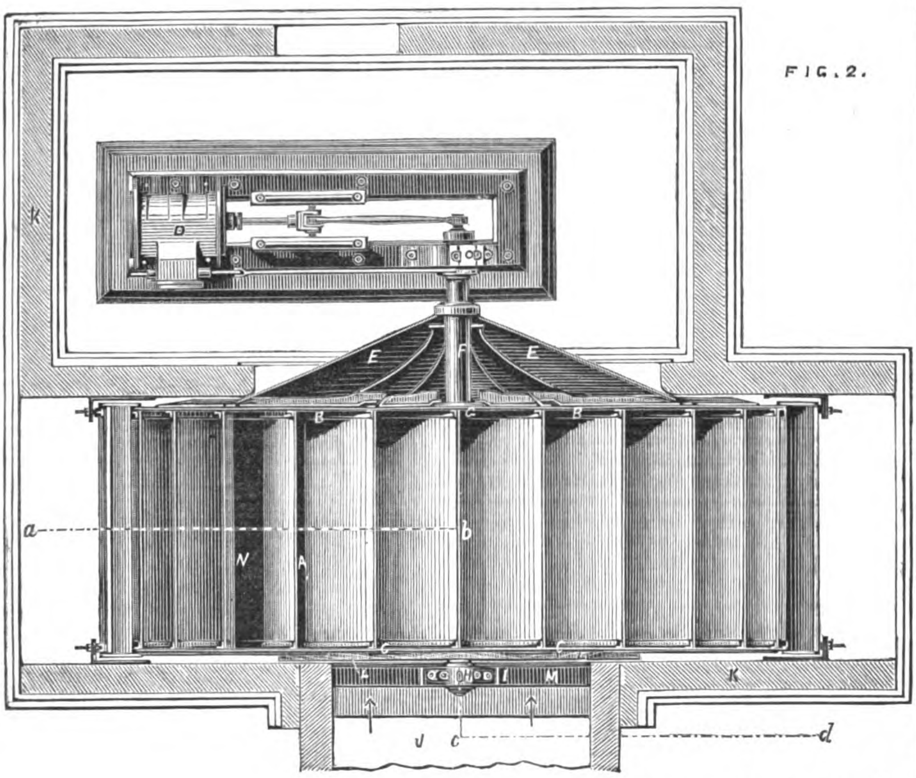

VENTILATING FANS.

MR. JOHN LLOYD, engineer to the Lilleshall Iron Company, near Shifnal, Salop, has just patented, through Messrs. Robertson, Brooman, and Co., patent agents, of 166, Fleet-street, some improvements in the construction of ventilating fans. The object of the invention is to construct the fans with a series of vanes or blades of varying lengths, and fitted between two discs. One of the discs is solid, while the other has a hole in its centre, through which the air is drawn. The solid disc is fitted to a face plate, by which it is rotated, or a shaft may be fitted through the solid disc, and bolted on the inside of it. Each blade is formed of a segment of a circle.

In the accompanying engraving, fig. 1 is a half sectional view taken through the line *a b c d* of fig. 2, which is a plan view of the same. A A are the blades, which are fitted to the insides of the discs B C; these blades are arranged in segments of circles from the outer edges of the discs to near the central portions, and are secured to them by means of angle irons and rivets. The disc D, which is nearest the engine D, is perfect, and has connected to it arms E, which are spread outwards near the centre for the purpose of being fitted to the axle or shaft F, by which the fan is rotated. The shaft is likewise connected to the disc B by means of a collar or socket G, which forms an additional support to the fan, and ensures its steadiness while revolving. The shaft passes through to the opposite side of the fan and finds a bearing in the plummer block H, which is fitted on the pedestal I. The disc C has the opposite sides of the blades A A attached to it by angle irons and rivets in a similar manner to the disc B. There is a hole in the central part of the disc C, which is in connection with the drift or air shaft or passage J, and as the fan revolves it draws air through the passage into and between the blades and drives it out into the atmosphere from the periphery.

To ensure the fan working as closely as possible to the wall K of the drift to prevent a re-entry of air, a ring of wood L is fitted on the outside of the disc C, which just touches the wall without producing unnecessary friction, and that part of the wall is covered with cement, in order to obtain a comparatively smooth surface for the wood ring to work against. In some cases, Mr. Lloyd fits a girder M across the opening of the drift and secures the pedestal to it. The girder gives rigidity to the fan shafts, and also serves to strengthen the wall or structure. Inside the discs B C are fitted shorter blades N N, which spring from the periphery towards the centre. They are fastened to the discs in a similar manner to the blades A A, and act as spreaders or dispersers of the vitiated air which accumulates at the centre of the fan. The periphery of the fan is enclosed by a series of adjustable flaps P, which are held in position by plates Q fitted on the side walls; one end of each of the flaps is hinged or jointed to the plates while the other ends are fitted to threaded rods, which pass through projections on the plates. Nuts are placed on the rods, so that the height of the free end of the flaps can be regulated to suit the speed at which the fan may be rotated in order to produce a steady withdrawal of the air from the mine or other place to which it may be fitted.

IMPROVED CARRIAGE LAMP.

SOME improvements in carriage lamps have been patented by Messrs. Howes and Burley, of Birmingham, and which are shown in the annexed engraving. Fig. 1 represents a portion

FIG. 1.

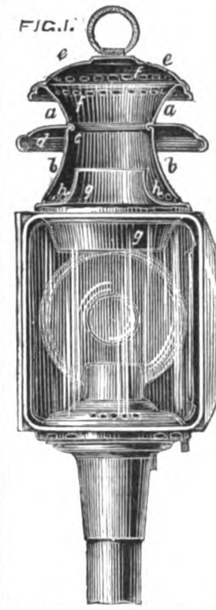

FIG. 2.

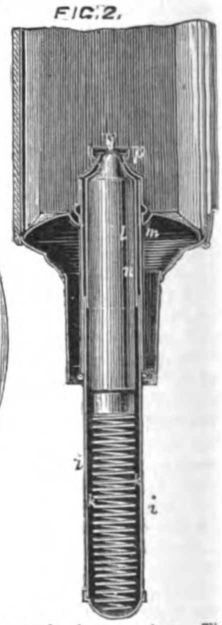
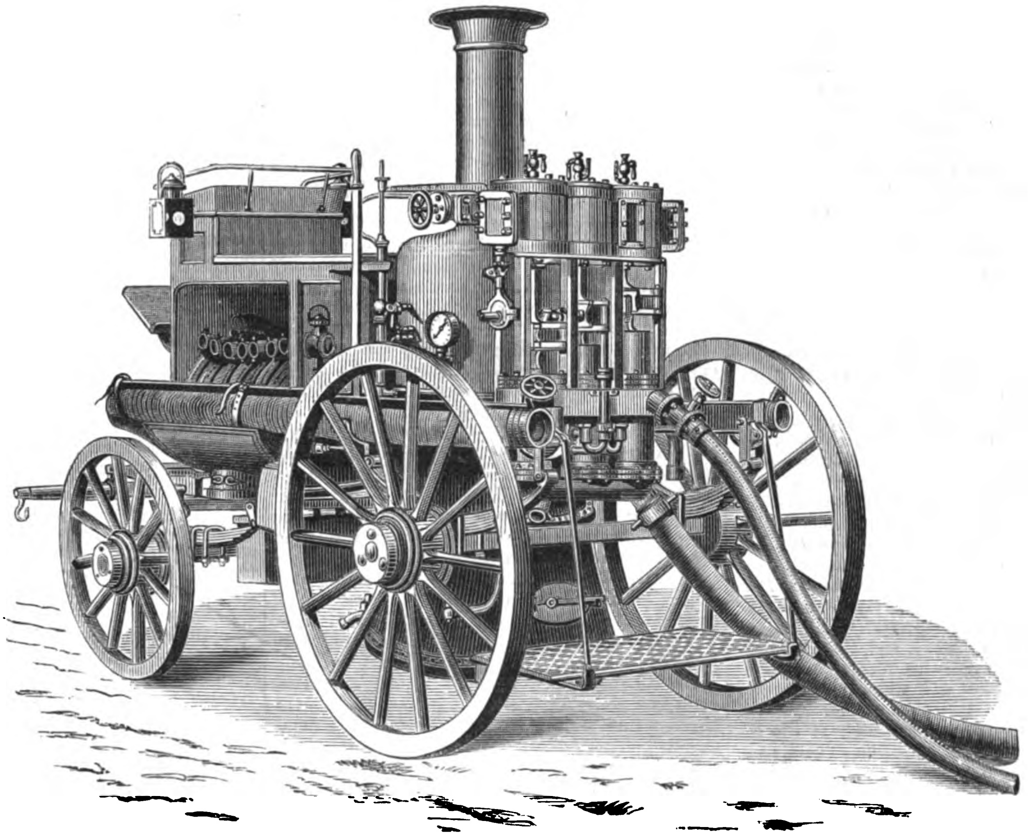


of the improved lamp, partly in section. The body of the chimney is made in two parts *a b*, which are secured together by their edges being closed upon one another by pressure. The junction of the two parts *a b* is marked *c*, and the manner in which the edges of the parts are closed upon one another will be understood by an examination of the sectional part of fig. 1. The middle flange *d* of the chimney is also secured between the two parts *a b* at the same time that the parts are closed upon one another. The closing of the two parts of the chimney with the middle flange *d* between them is effected by means of dies worked in a press. The top hollow flange or cover *e* of the chimney where it joins the top of the body is secured by pressure in the same way as the body and middle flange. In the upper part *a* of the chimney and top hollow flange *e* are holes *f f* for the escape of the vitiated air from the lamp instead of having holes in the vertical sides of the chimney for that purpose, as is usual. The position of the holes *f f* prevents the entrance of

EQUILIBRIUM STEAM FIRE ENGINE FOR DARLINGTON.

BY MESSRS. SHAND, MASON, AND CO.



air into the lamp in windy weather, and thereby ensures a steady flame. At the bottom of the ordinary chimney and projecting into the lamp and situated over the flame is an internal chimney *g*. At the bottom of the outer chimney of the lamp is a series of holes *h* through which air is admitted around the inner chimney *g* for keeping it cool. By the use of an internal chimney *g* over the flame an increased draught is obtained and a brighter light from the candle secured.

Fig. 2 represents in section the lower part of a carriage lamp provided with Messrs. Howes and Burley's arrangement for preventing the sticking of the candle in the lamp. *i* is the movable candle tube of the lamp in which the spring *k* for forcing up the candle is placed; *m* is the fixed candle tube, and *n* is the supplementary tube between the candle tube *m* and candle *l*. The supplementary tube *n* is contracted at top and rests on the top of the candle. It will be seen that the wax or tallow from the candle *l* is prevented by the supplementary tube *n* from coming in contact with the interior of the fixed candle tube *m*, and hence the sticking of the candle in the tube *m*, as frequently happens, is prevented. The inventors apply to the nozzle of the candle tube *m* a cup *p* in which the wax or tallow from the candle, should it gutter or run, accumulates. The wax or tallow is thereby prevented from passing on to the nozzle of the candle tube *m*.

Messrs. Howes and Burley's invention also consists of the following improvements in lamp irons and the parts of carriage lamps by which they are connected to the irons. The lamp irons consist of an arm fixed to the carriage having at its end a short tube or barrel into which the socket of the lamp fits. The barrel of the irons is lined with a metal not liable to corrosion by moisture. By this means the sticking of the candle socket of the lamp in the barrel of the arm is prevented. A rim is also made at the bottom of the barrel of the lamp iron to prevent the losing of the candle tube and spring by falling from the barrel. In order to fasten the socket of the lamp more effectually in the barrel of the lamp iron the rim at the bottom of the socket is capable of turning upon the barrel, and a screw thread is cut in the interior of the rotary rim. On the socket of the lamp is cut a screw thread of a size proper to take into that in the rotary rim of the barrel. When the lamp socket has been put in its place in the barrel by turning the rim at the bottom of the barrel the lamp is securely fastened to the rim and barrel.

THE MONCRIEFF GUN CARRIAGE.

YESTERDAY week a trial was made at Woolwich of the first service 7-inch barbette gun carriages constructed upon the Moncrieff principle. Since the system was tried at Shoeburyness, various modifications have been introduced by which the carriage has been simplified. The pawl and brake can now be worked by one hand, and the carriage altogether involves less labour in handling. On the present occasion five rounds were fired, one with 18lb., and the rest with 22lb. charges, and 110lb. shot, to test the recoil and action. The carriage worked with perfect success, although no previous adjusting round had been fired, as is the practice with ordinary carriages. The recoil was easy and gentle, the gun coming down exactly to its bearings with the recoil from the battering charges to the force of which it was theoretically adjusted, and with the 18lb. charge it came down far enough for loading. The carriage was not put upon racers but was laid down on the wood platform, the trucks resting upon pieces of smooth, flat iron. There was no pivot nor anything to prevent it driving back during firing; nevertheless, not the slightest backward movement was perceptible, the inference being that racers may be dispensed with and the carriage placed in position on a cast-iron floor, as has been proposed by Captain Moncrieff. Altogether the experiments were considered highly satisfactory.

STEAM FIRE ENGINE FOR DARLINGTON.

THE accompanying engraving represents an equilibrium fire engine, which is now in course of construction for the town of Darlington. Mr. Pease, of that place, having determined on presenting to his town a steam fire engine, deputed Mr. Cudworth, of the South-Eastern Railway, to select one. After careful investigation, Mr. Cudworth decided to recommend the equilibrium steam fire engine of Messrs. Shand, Mason, and Co., and that firm are now constructing the engine we have engraved. It consists of a treble set of pumps, which are worked direct by a corresponding set of treble steam cylinders, the whole fixed to the boiler and forming a most compact and equable steam fire engine. By using three pumps a perfect uniformity is obtained in the flow of water through the hose and suction pipes, avoiding all shocks of the engine or pipes, and producing a jet quite as steady as those obtained by pressure from gravitation. The boiler, by an arrangement of inclined water tubes, combines the greatest possible rapidity in generating steam with economy of fuel, and is extremely simple in construction. This engine is similar to that supplied by Messrs. Shand and Mason to the Local Fire Commission of Hamburgh in October last, and which was described by us at page 246 of the present volume. The performances of that engine are thus referred to in the Hamburgh "Nachrichten," which reports the official trial before the local authorities:—"The water was drawn from a reservoir in the neighbourhood of the English planke (a street), and the height to which the water should be projected was to be ascertained by marks on the church tower, but, owing to the exceedingly strong wind which prevailed at the time, the height could not be ascertained. At half-past nine the trial commenced with the lighting of the fire, and in the space of seven and a half minutes there was 100lb. of steam pressure, and the engine began her duty in earnest through a line of hose 80ft. long; the steam pressure quickly rose to 120lb., and was kept at this pressure with the most perfect ease. After this the fire engine was taken to the harbour, when it was again tried, and did her work in a most excellent manner. It drew water from the river Elbe for a depth of 20ft., and, notwithstanding this, it threw the water to a very considerable height. At both trials, the president of the deputation, Senator Peterson, as well as several other members of the deputation, were present, and expressed their entire satisfaction at the results attained."

A NEW steamship, the "Alnwick Castle," built by Messrs. C. Mitchell and Co., Low Walker, on the Tyne, for the Northumberland Steam Shipping Company, was launched on Saturday. She is intended for the Indian trade, *via* the Suez Canal, and she has been specially constructed for the purpose. Her rig will be that of a four-masted schooner, and she will have engines of 600-horse power. If the Suez Canal proves a safe waterway for steamers to proceed from the Mediterranean to the Red Sea, it in likely that a good deal of new iron steam tonnage building for Tyne shipowners will be employed in the East India trade by this route.

INDIARUBBER HORSESHOE.

At a recent meeting of the Liverpool Polytechnic Society, Mr. J. T. King, President, in the chair, the following paper by Mr. Hay Downie, on Downie and Harris's Patent Shoes for Horses, was read :—

What is the best style of shoe for a horse? and what is the best method of applying it? are questions that have long puzzled the whole veterinary faculty; and while much has been said, little has been accomplished towards the achievement of a practical result. Many inventions of a more or less meritorious nature have from time to time been brought before the public, but either owing to defective construction, the difficulty experienced in applying them, inutility, or other general inaptness, have failed to meet the end in view, leaving the unfortunate quadruped to trudge along under all the disadvantages of the old system. The matter has at last received a highly satisfactory solution in the invention of the rubber horseshoe by Mr. Hay Downie, of Corstorphine, for which, in conjunction with Mr. Harris, of Castle Mills, Edinburgh, he has obtained a patent.

The shoe is an ingenious and novel combination of iron and rubber, and the chief features of the invention are, first, a light narrow shoe of wrought iron without either tips or coulthers, of the same thickness from toe to heel, and having a perfectly level bearing throughout; second, an india-rubber web, which is placed between the shoe and the hoof, covering the whole of the foot, and fitting close round the frog, which is left exposed. Part of the web which lies immediately beneath the shoe is composed of some material which, united with the rubber, is non-elastic, and, therefore, has no power to draw or otherwise loosen the nails; third, that part of the web which touches the inner rim of the iron is much thicker than the rest of it, and forms a cushion, which at the toe stands 1-16in. above the tread surface of the iron, and gradually slopes upwards to the heels, where it stands ⅛in. above the tread surface. The shoe is fastened on in the ordinary way, but the nails are so far forward as not to interfere with the proper expansion and contraction of the hoof when in action, and when finished has a very neat appearance.

Although the advantages arising from the use of the shoe just described are many and obvious, it might be well to enumerate a few of them, and endeavour to show to what extent the invention is a cure and preventive of existing evils. It is in our large cities, where thousands of horses are daily at work on the hard paved, steep, and slippery streets, that the benefits of the system become most apparent. Every step taken by the animal gives a shock to the muscular system of the limb, and creates a heat in the hoof, which in a comparatively short time operates with telling severity. As already stated, the rubber projects beyond the tread surface of the iron part of the shoe, in certain proportions between the toe and the heel, thus coming first in contact with the ground and effectually preventing concussion, the results of which are so much to be deplored.

No one can have failed to notice the pain and difficulty experienced by omnibus, cab, and draught horses in ascending and descending steep and slippery inclines. Their strength is not so much taxed in pulling their load as in maintaining their footing, in endeavouring to do which a great strain necessarily falls on the hind legs. To this severe exertion of the hind legs may easily be traced spavins, sprains of the hock, back, sinews, and fetlock joints, and even severe and lasting injury to the spine and loins. Here again the projecting part of the rubber comes to the animal's assistance, affording a secure footing on the smoothest pavement and greasiest causeway. Even on ice the horse will walk with the most perfect safety and comfort. The experiment has been successfully made, accordingly the necessity for sharpening in frosty weather is entirely obviated. These tests clearly prove the invention to be a complete safeguard againt slipping, and a horse going at a brisk trot can thus be brought to a stand almost instantaneously, without a single shuffle. The cushion of rubber keeps the foot moist, preserves its natural level, and encourages the growth of the hoof. The shoe has conduced largely and most effectually towards recovery of lameness, groggy horses especially becoming comparatively sound. Leaving the streets of the city, the accruing advantages on the macadamised country road are, the effectual prevention of stone carrying and balling with snow. The rubber pad is also impenetrable to sharp granite, slag, or other road metal, old nails, and even broken glass.

In shoeing, any inequality is rasped down, and the knife is little used, therefore the foot suffers but little or nothing by the process of paring, which may be accounted a matter of no little importance, when, as is well known, by many, if not all other systems, in order to obtain a fit, the hoof is so much cut away as to inflict on it a permanent injury. This is at least very frequently the case. The base of the frog and heels are cleared out, that the rubber may fit in and form a stay between them. The frog is preserved entire and allowed to attain and keep its natural growth, while burning the hoof is never resorted to. In regard to the mode of fastening the shoe, it has been stated that the nails are so far forward as not to interfere with the proper expansion and contraction of the hoof when in action—a circumstance of no mean consequence. By the old system, the foot is all but encircled by the shoe, and is thus so tightly bound as to render expansion and contraction almost impossible.

Many veterinary surgeons and farriers have expressed their unqualified approval of the invention, and many gentlemen who have tried it on their horses testify to its general excellence, but perhaps one of the strongest proofs of its worth is its having been awarded a silver medal by the Highland Society of Scotland, at their recent show in Edinburgh. It is now becoming an article of very general use, and a company has been formed to prosecute the sale of it. Though somewhat more expensive at first than the old system of sh eing, when it is taken into consideration that one set of rubbers last out two and three sets of irons, it is cheaper in the end. Possessing, as it does, many merits, it cannot fail to become not only generally but universally used, and that not only in Great Britain but throughout foreign countries. Thus in a short time a large reduction may be hoped for all the ills, tear and wear, that horse flesh is heir to.

The Chairman then exhibited several of the shoes. He explained that the distinguishing peculiarity of the patentee's invention was allowing the rubber to project over or beyond the surface of the metal, so as to give an elastic tread and prevent the horse from striking its foot upon the ground with a dead blow, and said it had been found in practice that the rubbers would last out two metals. He stated that the patent shoes had been in use for about the last six months. In answer to a question as to the effect of using them in frosty weather, he stated that horses had not the same tendency to slip with them.

Mr. Arnott said that whilst at the Agricultural Show at Edinburgh, he was informed by a gentleman who had used them for his horses, which travelled over the heavy road from Leith to Edinburgh, that their adoption resulted in a very great saving. The principle now admitted to be correct in reference to horse-shoeing was to enable the frog of the hoof to get hold of the ground. The practice hitherto had been to shave off the frog, and so prevent the horse's foot from properly reaching the ground. But now the horse had got fair play in this respect. The next improvement would be to give the animal liberty with his head, for unless he had that the horse was cruelly treated. In America there were at the present time societies the object of which was to prevent the use of bearing-reins.

GUY'S TABULAR CALENDAR.

A very useful adjunct to the office, the library, or, in fact, to any place of business, has just been registered by Mr. T. J. Guy, of 252, Goswell-road, London. It consists of a framed almanack and monthly memorandum, with vacant spaces for memoranda for every day throughout the year. A tin frame about 12in. wide by 10in. deep carries a set of six cards, each side of which is divided into spaces for all the days of the month, one side of each card being devoted to each month. When one side of the card—say that for January, 1870—is filled it is reversed in the frame, the back showing the month of February. As each card is filled it can be placed at the back of the rest and thus be preserved for reference. A socket is attached to the frame in which a pencil is kept, so that this useful calendar and memorandum tablet is rendered complete in all respects.

At a recent meeting of the leading agriculturists of Notts it was resolved to establish a chamber of agriculture in that county. An influential committee was appointed to carry out the object of the meeting.

FURNACES FOR MELTING STEEL.

Mr. J. Suter, of Hereford, and Mr. T. Hinde, of Fownhope, near Hereford, have patented an invention which consists in constructing furnaces for melting steel and for other purposes, and in the combustion of fuel in the furnaces, by which means great economy of fuel is said to be effected, a higher temperature obtained, and great control over the action of the furnaces at the same time secured. These improvements are also applicable to the furnaces of steam boilers. The furnace is constructed of three principal parts, namely, of a gas-generating chamber, a combustion chamber, and a superheating chamber. In the first or gas chamber, the solid fuel is converted into gaseous fuel by being ignited and supplied with a sufficient quantity of air to convert the carbon of the fuel into carbonic oxide. The second chamber of the furnace consists of a reverberatory chamber, into which gaseous fuel produced in the first chamber mixed with the requisite quantity of air for combustion is burned. In the third or supplementary chamber the gaseous fuel is heated prior to being burned in the combustion chamber. The gas-generating chamber is of iron lined with fire-brick, and having an opening at bottom through which the clinker can readily be removed; or the clinker may be fluxed out by charging a little lime with the fuel.

Fuel is supplied to the gas-generating chamber by an opening at top closed by a valve, which permits of the introduction of the fuel without material loss of gas. The requisite quantity of air is introduced into the gas-generating chamber from a fan, and is delivered into the chamber by a tuyere. In order the more effectually to bring the air into contact with the ignited fuel where the fuel is very small or in a fine state of division, it is delivered into the chamber by a series of small openings in the tuyeres instead of by one or two large openings. The combustion chamber, in which the gaseous fuel is burnt, and in which the steel is melted or the other operations of the furnace performed, has a size and form suitable to the particular use to which the furnace is applied. The gaseous fuel is heated before it is introduced into the combustion chamber, so as to raise its temperature, and thereby produce a more intense heat in the furnace, either by passing it through heated tubes or by allowing it to undergo combustion. When the gaseous fuel is heated by the former method, a heating chamber is constructed above or in connection with the combustion chamber, through which heating chamber the waste heat from the combustion chamber is passed. Fire-clay tubes passing through the heating chamber conduct the gaseous fuel to the combustion chamber, which gaseous fuel is superheated in its passage through the tubes. When the heating of the gaseous fuel is effected by its own combustion, atmospheric air is mixed with it and it is ignited. The gaseous fuel which has thus been burned is passed through ignited carbonaceous matter, whereby it takes up carbon, and becoming revivified or reconverted into combustible gas passes to the combustion chamber strongly heated and with its full combustible power. By heating gaseous fuel in the ways described an intense heat is produced in the combustion chamber. When the furnace is used for reducing metallic ores the gaseous fuel is not superheated by the waste heat from the combustion chamber, but the gaseous fuel passes into and through the combustion chamber to the superheating chamber and is burnt in the superheating chamber.

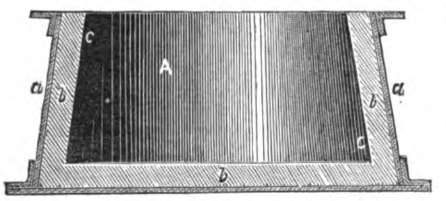
In applying these improvements to the furnaces of steam engine boilers, the superheating of the gaseous fuel is unnecessary. By varying the quantity of air mixed with the gaseous fuel during combustion, the character of the flame produced may be varied so as to possess either a reducing or an oxidising action. As a convenient means of ascertaining the character of the flame, the inventors employ in the furnace a small lump of coal and a lump of peroxide of manganese. When the flame has an oxidising character, the gaseous fuel volatilised from the coal burns with a bright light while there is no apparent action on the manganese. When the flame has a reducing character, there is no flame from the coal, but the lump of oxide of manganese becomes intensely ignited by the combustion which takes place on its surface between the oxygen evolved from it and the carbonaceous matter of the gaseous fuel.

We learn that the Postal Convention with England has been concluded at Washington, providing for the reduction of the single letter postage to 6c. The Convention will come into effect on Jan. 1, 1870

OBTAINING MALLEABLE IRON OR STEEL FROM CAST IRON.

MR. J. BERGER SPENCE, of Manchester, has patented an invention which relates to that method of obtaining malleable iron or steel from cast iron in which nitrate of soda or other similar chemical salts are used for oxidizing substances contained in the iron. It consists in a method of using the salts whereby their decomposition is to a certain extent retarded. For this purpose he brings the nitrate into a more or less solid body before the melted iron is allowed access to it. The annexed cut represents the vessel which is to contain the nitrate of soda. It consists of a metallic casing *a* lined with fireclay or brick *b*, and the sides may be inclined outward from the top as shown at *c*. Into this vessel A the nitrate of soda or other salt is placed and fused therein, or it may be previously fused and then poured into the vessel. When cold this salt will be more or less in a solid block. The whole is then removed to the bottom of the furnace and confined to it by clamps, the joints being luted. The molten metal to be converted being now poured through an aperture in the furnace decomposes the salt in the vessel, but as that salt is in a solid block, in contradistinction to the disintegrated condition of that usually employed, such decomposition will be retarded, and the products will not to so great an extent be driven off without producing useful effect.

The solidification of the salt may be obtained by fusion as above mentioned, but that object may also be attained by pressure, and this process may be effected in the vessel A or in separate moulds to be afterwards adapted thereto. As shown in the engraving, the sides of the vessel A are bevelled



The object of this is to prevent a rising of the cake or the passage of the metal beneath it, but when this form of vessel is adopted, the salt must be fused in it, or poured into it in a fused state, or the vessel must be made with a movable part to admit of the separately fused cake being adapted, and the like keeping down of the cake may be effected by projections.

THE MONITOR-TURRET AND THE CASEMATE.

AN opportunity of instituting a direct comparison between the monitor-turret and the fixed casemate has at last been furnished by the completion of the Turkish armour-clad war vessel "Moyini Zaffre," which was launched on the Thames last June. The building and arming of this ironclad being the result of the joint efforts of Sir William Armstrong, Samuda, and Ravenhill, we have a guarantee that whatever merits the fixed casemate system possesses have been fairly developed in this the latest attempt to supersede the monitor. The United States "Army and Navy Journal," from which the present article is taken, illustrates the two systems by a plan of the "Moyini Zaffre" (fig. 1)—length, 230ft.; beam, 35ft. 6in.; armament, four 12-ton guns; and a plan of a monitor with two turrets (fig. 2)—length, 230ft.; beam, 35ft. 6in.; and armament, four 24-ton guns. It cannot fail to be noticed—continues our contemporary—on careful examination of our engravings, that the planning of the casemate of the "Moyini Zaffre" shows much thought and elaboration; also that the complication which characterises its form is evidence that the planner was dealing with a difficult subject. Nor can the attentive observer fail to see at a glance how imperfectly the disadvantages attending the elongation and immobility of the battery, viz., the limited horizontal range of the guns, have been overcome by the combination of curvatures and angles resorted to by the constructor of this substitute for the monitor-turret. Our engraving, besides representing a top view of the "Moyini Zaffre," accurately drawn to scale, also represents top view of a monitor provided with two turrets of the same diameter as those of the "Passaic" class, viz., 21ft. internally. The length of the Turkish vessel is 230ft., with 35ft. 6in. beam. The monitor, for the sake of exact comparison, has the same dimensions; but the thickness of its armour is greater than that of the former, and so proportioned that the weight of armour of both vessels is alike. The freeboard of the "Moyini Zaffre," as in all

THE MONITOR-TURRET AND THE CASEMATE.

FIG. 1.

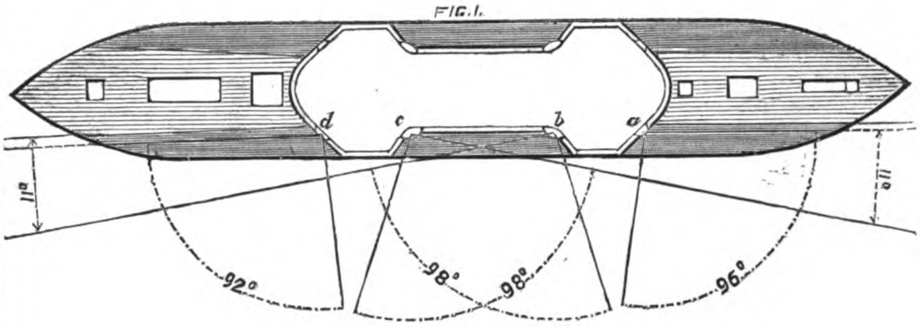


FIG. 2.

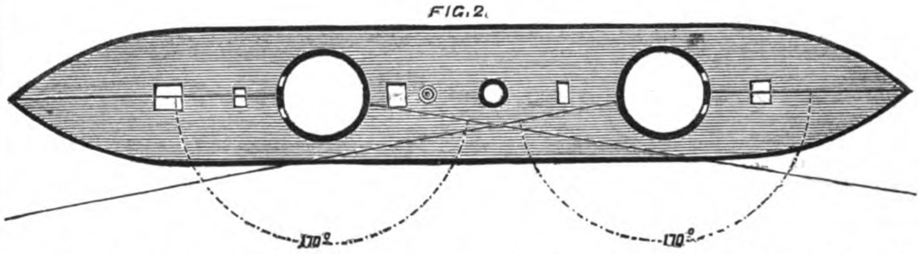

ironclads built by English engineers, is several times higher than that of the monitor, and, consequently, deeper armour below water must be applied to afford protection; increased rolling being the inevitable result of high freeboard. Referring to the plan, it will be seen that the circumference of the fixed battery is greater than that of the two turrets in the ratio of 25 to 15.

The English mechanical journals point with apparent satisfaction to the circumstance that this casemate ship, which is intended for the defence of the Bosphorus, has armour-plates generally 6in. in thickness, the whole of the battery (backed with wood) being cased with 5-inch plates. The battery, though pierced for eight guns, will only carry four of Armstrong's 12-ton rifles. The intention being to transfer the pieces from one side of the battery to the other during action, Sir William has unquestionably reached the limit of weight, considering the difficulty of changing sides with the rapidity called for during contest with screw-propelled assailants. But the constructor of the monitor-turret, which, as our engraving shows, commands 340deg. of the horizon, is not hampered by considerations of weight of metal, a 24-ton gun, or even one weighing 48 tons, being pointed as readily by turning the turret as the lightest field-piece. Accordingly, the monitor which our engraving represents is mounted with four 24-ton guns. Making proper allowance for the greater area of side armour and battery plating of the "Moyini Zaffre," it will be found that our double-turreted monitor will, on the same draught of water, support 10-inch thick side armour, 15-inch thick turret plating, and carry four 24-ton guns. The greater security—we might say, the impregnability—thus attained by the monitor form is, however, only a part of the advantage of this system over that which is represented by the Turkish ironclad—the latest endeavour of our transatlantic rivals to demonstrate that the conflict at Hampton Roads was not, after all, so significant as supposed. Impregnability and calibre, although very important, by no means decide the superiority of armoured vessels—horizontal range is in many cases of equal importance. A monitor hull provided with a fixed battery may be made as impregnable as a complete monitor, but at least two-thirds of the guns of such a craft will be ineffective in battle. Samuda, evidently, was fully aware of the impotency of his artillery, owing to limited horizontal range, when he adopted the complicated form of the battery of the "Moyini Zaffre."

We now propose to consider in detail this question of horizontal range, and beg the reader to inspect closely the extent of ranges marked on our engraving for each gun separately. We will first consider the ranges obtained by the fixed battery of Samuda's construction. To avoid confusion, we have lettered the several ports *a b c* and *d*, the first letter denoting the forward port of the battery and also the muzzle of the piece belonging thereto. Beginning with the first-mentioned port, it will be seen that each gun respectively ranges over a field of 96, 98, 98, and 92deg. Referring to the plan of the monitor, it will be seen that each of the four guns sweeps a field of 170deg. It should be observed that the ranges marked on the engraving have reference only to the starboard side of the line of keel.

It will be proper, before assigning a numerical value to the efficiency of each of the systems under consideration, to remember that the real power of naval artillery is determined by multiplying the weight of shot by the horizontal range, the position of the vessel remaining constant. Modern target practice having demonstrated that a 24-ton gun is capable of throwing a projectile of 600lb. with adequate force and that a 12-ton gun is about the proper size for 300lb. projectiles, we are enabled, by applying the rule before mentioned, to determine with exactness the relative efficiency of the monitor-turret and the fixed battery or casemate. The power of the forward gun *a* of the casemate, will accordingly be represented by 300 × 96deg. = 28,800. In like manner, by multiplying the weight of the projectiles of the remaining three guns by their respective ranges, in degrees, we obtain a sum total of 115,200. Applying the same mode of computation to the monitor, viz., multiplying 600 × 170 × 4, we establish the important fact that the actual efficiency of the monitor is to that of the casemate vessel as 408 to 115. Apart from this superiority as regards the artillery of the monitor over that of the Turkish ironclad, the armour of both battery and hull of the latter is wholly insufficient to compete with the former. The inference therefore is obvious and irresistible, that the monitor represented by our engraving could readily destroy Samuda's casemate vessel. But it is not our intention to prove the worthlessness of the "Moyini Zaffre" as a war vessel, our object in discussing the subject being simply that of instituting a comparison between the two systems represented by our engraving.

Attention is called to the fact that, besides the limited horizontal range of all the guns of the "Moyini Zaffre," only one of the four can be pointed in the line of the ship's course; and that *c*, the only other gun capable of firing ahead, cannot point nearer than 11deg. of the line of keel. At a distance of a mile ahead, there is, consequently, a field of 1,200ft. which an assailant may occupy exposed to only one 12-ton gun. Chased by an enemy, the Turkish war-ship, with the Samuda-Armstrong battery, will be equally important; the gun marked *d* on the plan being her only defensive weapon. It will be found, on inspection, that the piece marked *b* cannot come nearer than 11deg. of the line of keel.

Let us now turn to the monitor. It will be seen that four 24-ton guns, two forward and two aft, fire in a direct line with the keel; there being no safe position, as in the case of the fixed battery, for the enemy's vessel to occupy. The entire field, viewed from stem to stern, as the plan shows, is swept by all the guns of the monitor. Bearing in mind that these powerful guns are protected by 15-inch thickness of iron, which, if applied in two thicknesses, is proof against any artillery yet conceived, while the 12-ton guns of the Samuda-Armstrong battery are protected by armour which a 7-inch rifle will pierce through and through, the argument in favour of the monitor-turret becomes overwhelming. It will be asked, in view of these incontrovertible facts, why do constructors advocate the fixed battery? We know of no other reason than the assumption that the joint between the rotating turret and the deck cannot be made secure. English engineers, relying on the accounts of the performances of the monitors published by the enemies of the Union during the war, apparently do not take the trouble to investigate the matter; while American experts, who have written about turrets—Mr. Eads, civil and mechanical engineer from St. Louis, among others—do not understand the subject, and evidently are ignorant of the most important facts connected therewith.

For instance, Mr. Eads, in a report to the Navy Department, informs the Secretary that "the baud round the base of the turret on the 'Dictator' weighs over 20,000lb.," and points out how much better this great weight of iron might be applied for other purposes. Now, this turret has no baud round its base, nor was it ever intended to have one! Mr. Eads also tells the Secretary that any downward swelling of the plating, produced by the impact of projectiles striking low, will stop the rotation of the turret by friction under its base. This assertion proves ignorance of the fact that the "Dictator" turret rests wholly on the four inner courses of plating (which cannot be swelled), and that the intermediate wrought slabs and outer plating (together 11in. in thickness) do not reach the deck, and therefore can, by no possibility, cause the predicted stoppage. Again, the apprehensions expressed in the report, with reference to the base of the pilot-house in connection with the rotation of turret, show that another very important circumstance had been overlooked, viz., that the turret is projected considerably above said base in order to protect it.

The fear entertained by Mr. Eads that the "pilot-house may be lost overboard" and the rotation of the turret stopped by the impact of "projectiles possessing insufficient power to overcome the inertia of the pilot-house itself" (held in place by a wrought iron shaft 14in. in diameter, and weighing upwards of 80,000lb.), will amuse our young friends at West Point and at the Naval Academy. Lastly, the rotation of the turret will, agreeably to the report, inevitably be checked should a shot strike it opposite the ends of the gun-slides, as the impact would cause binding of said slide, productive of general internal derangement. Mr. Eads, on this point, ignores the fact that in the "Dictator" and numerous other monitor ironclads, the ends of the gun-slides do not reach the turret wall, the gap between the end of the slide and the wall greatly exceeding the momentary yielding of the plating under the impact of projectiles. We have thus proved the untenable character of the principal objections raised, and exposed the misstatements which have been published relative to the monitor-turret, and, we believe, fully demonstrated its superiority over the Samuda-Armstrong battery of the "Moyini Zaffre."

CEDAR-WOOD CABINETS FOR SPECIMENS.

At a recent meeting of the Manchester Literary and Philosophical Society, Mr. Joseph Sidebottom made the following communication:—About fifteen years ago, I had a large cabinet made of forty-five drawers, to contain shells and carpological specimens, the drawers being made of pencil cedar. Very soon I found that the resinous vapour from the wood became deposited on some of the fruits and shells, making them appear as if they had been dipped in varnish. Chloroform appeared to be the only solvent, and the specimens were obliged to be washed with it. This became so bad that I had the whole of the drawers removed, and replaced with drawers of baywood. Sometime afterwards, Mr. Carter advised me to have the cedar drawers sized and papered inside, and a new cabinet made to contain them; accordingly he made me one to contain thirty drawers. These drawers were exposed to the air for twelve months, and very well sized inside, and papered, but the resinous vapour is still deposited on the objects in the drawers as before, and so far is a warning to everyone never to use pencil cedar for such a purpose. I should not, however, have thought this matter worthy of mention before the Section had it not been for the very curious and capricious way in which some objects are coated with this resin while others are left entirely free, and for which I am totally unable to account. In shells the genera Conus and Oliva are never touched by it, nor are Cyprea or Mitra, whilst Helix, Bulimus, and Pecten are coated over; this is the case when there are specimens of these and other genera in the same drawer. As this deposit is on the genera I have named, and never on the others, it would seem to indicate that the texture of some shells would attract the vapour and not others. But in the case of birds' eggs, the very strange manner in which some species are picked out as it were and others left, is most remarkable. In the owl's eggs, for instance, the barn owl is always free, while the tawny owl is covered with the varnish, although side by side. The song thrush is never attacked, and the missel thrush always.

THE number of Cornish pumping-engines reported for October is 20. They have consumed 1,556 tons of coal, and lifted 10·6 million tons of water 10 fathoms high. The average duty of the whole is, therefore, 45,900,000lb. lifted 1ft. high by the consumption of 112lb. of coal.

ANVILS.

THE face or table of anvils as at present made is often defective, having frequently hard and soft places after hardening, which face should be equally hard all over its surface, and the steel in some instances not being properly welded to the iron part or butt which forms the lower part, the anvil is thereby rendered unsound and not fit for use. Some improvements recently patented by Mr. J. N. Askham, of Sheffield, have for their object the removal of such defects, and consist in so making anvils that the face may be equally hard all over when finished, and in so casting or welding the butt to the head or upper table that the parts may be thoroughly amalgamated and the anvil made more durable at a less expense than hitherto.

Mr. Askham first prepares a model of the size and shape of the anvil to be produced. He then places it in a box, covers it with composition, and fills up the box with sand in the ordinary manner. After the model is removed and the sand perfectly dry (this being done in the usual way), he first pours in the molten steel to form the face or table, then, through the same aperture (after the steel on the table is sufficiently cool), he pours in a very mild molten steel, which flows over the table and gives the requisite toughness and solidity to the steel beck. After a proper time has elapsed, he pours in through another opening the iron or metal, which also runs upon the steel and forms the lower part or butt of the anvil, and a perfect amalgamation takes place between the iron and steel. The casting being complete, it is then finished in the ordinary manner for castings.

To harden the work, a large metal bosh or trough, 6in. or 8in. deep, is formed, in which is inserted a number of perforated sharp-edged bars of metal, on which the anvil is allowed to rest on its face or upper surface, either flat or slanting. A sluice communicating with a reservoir of water is then opened, and a force of cold water is allowed to flow upon the face by an upward cast and to pass under the anvil and over the bars to any depth required. By these means a much harder and more regular surface is obtained than by the present mode of manufacture. After this the surface is ground in the ordinary way.

OUR ORDNANCE AND PROJECTILES.

THE visit of Mr. Childers during the past week to the Whitworth Gun Manufactory at Manchester certainly appears to lend some confirmation to the rumour obtained to a certain extent in the navy, that the First Lord of the Admiralty is not quite so well satisfied with the present ordnance and their projectiles, mounted on the decks of our most recently commissioned ironclads, as may generally be supposed. We have been so long accustomed to praise so highly the coil-built gun and its ogival-headed Palliser projectile, that possibly the known defects of both have been ignored, and a false belief engendered of their infallibility. If the First Lord really entertains any doubt as to the efficiency of our present rifled naval gun and its projectile as an armour-destroying power in any future action between the ships of this and any other country at sea, he is not at all singular in that respect. For some time past a feeling has been growing up among naval officers and others acquainted with the subject, that, as we increased the size of our naval ordnance to 12, 18, 25, and now to 30 tons weight, we were drifting rapidly into a state of things that, as yet, was not by any means clearly defined or understood, but which it was just possible might be attended by two primary conditions that should render the guns of our ships practically harmless against an enemy's armour. The two conditions that threaten the efficiency of the artillery of the navy are—1, the acknowledged weakness of the gun itself, and its incapability to withstand the burning of very largely increased powder charges; and, 2, the defective properties of the projectiles and their brittleness. The weakness of the guns has been officially acknowledged by the order to give the turret guns for the new ship, the "Devastation," five tons weight of metal each in excess of those of the "Monarch," although the guns of each ship will be of the same calibre, and will throw the same weight of projectile. Their weakness was also very fully entered into and illustrated by Sir Joseph Whitworth, in a paper read by him before the British Association at Exeter, in August last, where he stated that the battering charges to which the 25-ton guns of the "Monarch" were limited was 70lb. of powder, when the charge due to their weight of metal was actually 150lb.

The defects of the ogival-headed projectile are known and admitted beyond all dispute. As, therefore, it is equally beyond dispute that all naval actions in future will be fought, not muzzle to muzzle, or with each pegging away at the thickest part of his enemy's armour and opposed to a concentrated fire from his heaviest guns, but, as far as may be possible on obtuse angles, and with the shot striking obliquely, where lies the fighting value of the ogival-headed projectile? If it strikes the side of an armoured ship obliquely—as in the firing at the turret of the "Royal Sovereign"—it flies off at an opposite angle to that of its flight from the mouth of the gun to the ship's side, for it has no "bite," or it breaks up into a thousand pieces. It has made good penetration into and through plating and targets, but with such work done by it the gun has been fired at right angles with the plate pierced, and then the cone-headed form of the shot enabled the latter to shoulder its way through. There is no record of oblique firing at armour plates or plated targets with the present naval gun, nor does there appear to be any record in existence, at the Admiralty or elsewhere, of the question having been closely considered in its application to ironclad fleets of the present day. It is to be hoped that Mr. Childers will, in this instance of the guns and their projectiles for her Majesty's ironclads, act as he has done in other instances at Whitehall—see into the matter personally, and form his opinions independently of any interested advice, however vehemently it may be tendered. The subject is one of such vital interest to the efficiency of the navy that no neglect or compromising measures can ever hide it from public sight.—"Times."

THE STEAM ENGINERY OF THE NAVY.

THE following condensed report of the Board of Civilian Engineers, appointed in 1863 to examine the screw engines of the navy, appears in the U.S. "Army and Navy Journal":—

Philadelphia, July 14, 1869.

Hon. George M. Robeson, Secretary of the Navy.

SIR,—In reply to your communication of June 25, 1869, of which the receipt has been acknowledged, I have the honour to report as follows:—

This board was appointed January 9, 1863, by the Secretary of the Navy for the purpose of having made "a more thorough examination of the screw engines, boilers, and condensers designed for the naval service by the Bureau of Steam Engineering."

On January 16, 1863, instructions were more fully given, embodying the special points on which information was desired.

On February 6, 1863, in obedience to the first part of these instructions, the board reported upon the designs for the screw machinery of the "Juniata" class of vessels, and on the paddle machinery for the "double enders," as follows:—

First, that the screw vessels of the navy should be capable of a speed of at least twelve knots per hour, under steam alone, and that their machinery should possess certain qualifications enumerated.

Second, that, judged by the standard thus laid down, the machinery designed by the Bureau for screw vessels was in type and in all other respects inferior to that in general use for naval and mercantile vessels; that it occupied more space in all directions, was more liable to derangement, used more steam, weighed much more, and was much more costly in construction, requiring also additional displacement to carry it.

Third, that in the engines of the "Juniata" class of sloops, at least sixty tons more weight and twenty per cent. more space was used than was necessary or proper.

Fourth, that the type of boiler (Martin's) used by the Bureau to the exclusion of others (and not used by other parties then or since) was in most respects inferior, and in none superior to other types; requiring to be at least one-third larger to equal the ordinary horizontal tubular boiler in power, with natural draught; of no greater economy on the average; of much greater weight and cost; incapable of being forced to an equal extent, and when forced continuously liable to serious derangement.

Fifth, that the paddle engines designed by the Bureau were open to serious objections as to proportions, excessive weight and cost, and inferior economy in the use of steam.

Finally, that the power of the machinery for these vessels, by changes in type and detail, could have been increased at least one-third over that attainable by the Bureau's machinery, without adding to the space occupied, decreasing the coal stowage, or equalling the total weight or cost.

Some of the foregoing conclusions having been questioned by the department, the board replied, February 20, 1863, now in detail, showing that, by comparison with machinery for either vessel in the navy designed by private firms, the "Juniata" actually occupied about twice the space, whether cubically or upon the floor, per unit of cylinder capacity.

On January 21, 1863, certain questions were addressed by the department to the board relative to engines, boilers, and condensers for vessels of the navy.

A reply furnishing the opinions of the board was made under date of February 19, 1863.

On February 13, 1863, the opinion of the board was requested by the department in regard to the propriety of modifying the regulations for the admission and promotion in the Engineer Corps of the navy.

A report was made upon the subject on the 20th of the same month.

On February 18, 1863, the board, in obedience to instructions contained in the communication of January 16, above referred to, reported upon the "7,500 ton iron-clads," designed by the Bureau of Steam Engineering, as follows:—

First, that the proposed machinery, when driven to utmost capacity, would only give a speed of twelve knots instead of sixteen, for which it was designed; or, in other words, was of less than half the required power; and that this result would be attainable only after essential modifications in detail.

Second, that the boilers proposed were of inferior design; and the use of one propelling screw for such a vessel was condemned.

Third, that by certain indicated changes in the boilers and screws, and by the use of properly designed "direct acting" engines (in lieu of the geared engines proposed, which were on the same general plan as those afterwards designed and put in the "Wampanoag" class by the Bureau) an absolute saving of space, weight, and cost could be effected, while the power would be doubled, and the speed of the vessel increased by at least three knots per hour.

As a result of this report the construction of several vessels for which bids had been received on these plans, was abandoned, and a saving of millions of dollars was effected.

On April 25, 1864, the department requested the board to examine and report upon the machinery of the "Pensacola," with a view to determine whether it should be repaired, modified, or removed; and in the latter case to recommend suitable machinery in its place.

On May 7, 1864, the board recommended that the latter course should be pursued; and after a critical examination of the designs for the "sixty-inch" engines and boilers (of which several unappropriated sets were then in hand), they recommended in preference the construction of new machinery similar to that designed by private parties and placed in the other vessels of the same date and class.

On July 26, 1865, the board was supplied with a copy of the contract for the construction of the "Algonquin," and was directed to institute a competitive test between her machinery (designed by private parties) and that of the "Winooski" (designed by the Bureau), with a view to determine if the stipulations of the contract had been fulfilled.

The board drew up a programme for this test, supervised the same, and on the 30th of March, 1866, reported the results attained, and their opinion that the contract had not been fulfilled; in consequence of which the machinery of the vessel was rejected by the department.

On February 19, 1863, the board was desired to experiment with the boilers on the "San Jacinto," both of which had been designed by the Bureau, for the purpose of comparing the merits of the type exclusively adopted by the Bureau, and that adopted generally for naval and commercial vessels throughout the world.

This test, the board, in March, 1863, declined making, not only for the reason that it would have detained a valuable ship for an indefinite period, at a time when every available resource of the navy was taxed to its utmost, but also because the boilers in question were not properly designed for comparison. The board, however, suggested as an alternative, that two experimental boilers should be designed by them, for a comparison, and be built by the department; announcing in such a case their willingness to undertake the necessary competitive tests.

On March 20, 1863, the department adopted this suggestion and ordered the construction of the boilers.

When these boilers were completely ready for trial, the department, by letter dated October 1, 1864, associated B. F. Isherwood, then chief of the Bureau of Steam Engineering, with the board, and a programme was adopted covering a large addition to the field of experiment originally contemplated by the board, and therefore requiring a considerably increased duration for the trials. As the department was at this time expending immense sums in the construction of new boilers, and the results of the experiments were constantly forwarded to the Bureau, and as constantly availed of by it, in modifying the designs for the boilers under construction, the original programme of experiments was still further enlarged from time to time, as the results of successive tests indicated the necessity of additional ones.

These modifications of design effected a great saving in cost of construction, in space occupied, and in weight, besides adding greatly to the efficiency of the boilers when built.

In no other way than by such experiments could this saving have been effected.

Thus reports of the board were made during these experiments almost weekly to the Bureau, and, at their conclusion, under date of October 26, 1868, a final report was made to the department, in which all the "logs" of the experiments were tabulated, the apparatus described, and the results presented in a comparative chart, thus avoiding a long and verbose comparison without detracting from its value to the engineer.

In conclusion, the reports of the board above alluded to have disclosed the general inferiority of the machinery designed by the Bureau of Steam Engineering to the practice of marine engine constructors in this and every other maritime country; from which practice it differed in essential points and with lamentable results.

These differences may be summed up, as consisting of the persistent use of an inferior type of boiler, inferior types of engines, highly improper proportions in their important details, and a very injurious and costly excess in weight over that required, or used by machinery builders of extensive practice and world-wide reputation.

All of which is respectfully submitted.

J. VAUGHAN MERRITT, Secretary of the Board.

The above summary is approved.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, December 8.)

IN the chemical market a moderate amount of business has been done, principally for export to the continental ports, which are frequently closed during the winter months. In the alkali trade no appreciable rise has yet taken place, but it is generally anticipated that a slight advance will occur in the beginning of the year, as in many instances producers have placed the greater part of their manufacture for the first six months of 1870, and are depending on a better price for the balance to increase their average. In minerals there is nothing special to communicate, the consignments from foreign ports being sufficiently large to keep uniform rates on the home production. There has been a moderate business doing in metals generally during the week; and in pig iron the excitement still continues, and a large trade has been done at advancing rates. Staffordshire iron is difficult to place at the price, except for a few first-class brands. Copper is in fair demand, and the present low prices are inducing orders. Tin is firm at the reduction. Lead selling freely at our quotation. Spelter continues dull, with no alteration in prices. Soda: Soda ash and caustic soda are firmer, and £7 for 48 of the former, and £13 for 60 of the latter is readily obtainable; soda crystals at £3 17s. 6d., and salt cake at 57s., are in fair request; bi-carbonate inactive at £9 5s. Nitrate of soda: sales at Liverpool are at £15 per ton. Potash: muriate is still in short supply, and prices rule at £7 7s. to £7 10s. for 80. Saltpetre: a better trade in foreign, at £23 for 5 refraction; refined at £26 10s. Alum: is firm, with a regular demand, prices remaining as before, £6 5s. for home, and £7 for export. Ammonia: considerable sales of sulphate, at £16 10s. for ordinary to £17 5s. for fine white; muriate at £22 to £23. Copperas: for green and rusty there is not much inquiry; in dry a considerable business has been done, at 50s. Pyrites: arrivals having been irregular have slightly deranged supplies in a few instances. Prices remain at 7d. to 8d. per unit for present consumption. Lime: phosphate rather quiet, at 52s. 6d. for 65; bleaching powder is firm at £8, and advancing, though contracts are still entered into at less; disinfectants bought freely, at £5 5s. for best quality. Manganese: meets with a slow sale, at old rates. Iron ores: hematite obtains 15s. to 18s.; oolitic finds an extensive market at 6s. to 8s. in Staffordshire. Guano: for best Peruvian, £13 7s. 6d. to £13 10s. is obtained; second sells at £11.

METALS.—Iron: Scotch pigs steady at 56s. 0d. to 56s. 1d. Cleveland, 46s. for forge, and 51s. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire bars, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: firm; English tough, £71 to £73; Chili slab, £67 to £68. Tin: English ingots, £119 to £120; Straits, £116. Lead: in good demand. P. G. best English soft pig lead, £19. Spelter: inanimate. English, £20 10s.; Silesian, special brands, £19 10s. to £20; hard spelter, for export, £16 10s.

THE "Journal de St. Petersbourg" of the 1st inst. states that on November 29, the Tamboff-Kozloff Railway had been provisionally opened, that the first train passed from Kozloff to Tamboff in the presence of a large concourse of people and of the troops of the garrison, and that the regular service of the line will commence very shortly.

Legal Intelligence.

COURT OF CHANCERY, LINCOLN'S INN.

DECEMBER 8.

(Before the LORD CHANCELLOR and Lord Justice GIFFARD.)

RE YATES' PATENT.

THIS was a petition to the Lord Chancellor for the sealing of a patent. Mr. W. Yates, on June 15 last, applied for letters patent for an improved method of supplying air to the fire of a furnace. The sealing was now opposed by Mr. Fletcher, who had obtained a patent for the same purpose on April 5 last. He had not opposed the granting of the patent to Yates when the matter was originally before the law officer of the Crown, but he explained this by saying that he did not know of the application till too late. He consequently, having no other course left open, opposed the petition of Yates to the Lord Chancellor for the sealing of the patent. The Lord Chancellor, when the matter came before him, referred it to the Solicitor-General to determine whether, under the circumstances, a patent ought to be granted to Mr. Yates. The Solicitor-General decided that Mr. Fletcher's invention, previously patented, was the same as that of Mr. Yates, and consequently that no patent ought to be granted to the latter. The matter now came on again to be mentioned, the decision of the Solicitor-General being conclusive on the merits.

Mr. Macrory, on behalf of Mr. Yates, only urged that his petition ought to be dismissed without costs. There was no suggestion of bad faith on his part, and, in fact, he knew nothing of Fletcher's patent till after the application for the sealing.

Mr. T. Aston appeared for Mr. Fletcher.

The Lord Chancellor saw no reason why the petition should not be dismissed in the ordinary way with costs. The person who failed ought to pay the costs.

VICE-CHANCELLOR'S COURT.

DECEMBER 2.

(Before VICE-CHANCELLOR SIR R. MALINS.)

NORRIS V. THE BIRMINGHAM SMALL ARMS COMPANY.

MR. THEODORE ASTON (with whom was Mr. F. Harrison) moved to restrain the defendants from manufacturing certain arms, alleged to be an infringement of the plaintiff's patent for improvements in the apparatus for breech-loading arms generally. An inspection also was asked for. These arms were for exportation to Russia.

Mr. Cotton, Q.C., for the defendants, asked for security for costs, which being given, he offered to keep an account, but asked for time, the manager and secretary being in Russia.

After some discussion,

The Vice-Chancellor directed the motion to stand over for a fortnight without any terms as to inspection, the defendants keeping an account. It was impossible to decide a question of patent except upon affidavits on both sides.

Correspondence.

HOWARD'S BATTERY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Instead of constructing the zinc and copper cells in Howard's battery as described in the MECHANICS' MAGAZINE of October 1, 1869, I take a plate of zinc and a plate of copper and simply bend them into a cylinder, which will answer the purpose apparently quite as well as going to the trouble and expense of making cells. I varnish one side of the zinc plate previous to bending it, and it will, perhaps, be better to tie a piece of twine to keep it in a cylindrical form; the copper will do so without the twine. I have reversed the arrangement described by putting the copper rod and cylinder into the porous cell, and the zinc rod and cylinder into the outer jar. This battery is very cheap, and easily constructed. It seems to be much easier to obtain a powdery deposit than a reguline deposit of zinc.—I am, Sir, yours, &c.,

JAMES HOWARD.

95, Cross-lane, Salford, December 7.

Meetings for the Week.

MON.—Society of Engineers.—Annual General Meeting for the Election of Officers for the ensuing year, at 7.30 p.m.

TUES.—Institution of Civil Engineers.—On "Ocean Steam Navigation, with a view to its further development," by Mr. John Grantham, M. Inst. C.E., at 8 p.m.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

"A Seafaring Man of the Modern School" has not enclosed his name and address, which are not required for publication, but as a guarantee of good faith. Upon receiving these his letter will appear, and we doubt not that he information he asks will be forthcoming.

ERRATUM.—As some of our readers may have been puzzled with the curves (as compared with the tabular figures) in the second diagram which accompanies Mr. Strachan's paper on the Height of the Barometer, &c., published in our last issue, we may mention that the engraved block was accidentally reversed.

Naval, Military, and Gunnery Items.

WE learn by the Bombay papers that orders have been received from the India Office for the Bombay native army to be reduced by five regiments; and it is also said that the Madras army is to be reduced by seven regiments of native infantry. Besides these important reductions others are reported to be in contemplation.

WE, "Portsmouth Times," understand that several shipwrights who have been discharged from the dockyard have been re-entered as "mechanical labourers" at 18s. per week, and that they have found themselves expected to do precisely the same work as that on which they were previously employed at 27s. per week. We are also informed that labourers who were earning 14s. per week have been discharged, but have been allowed to enter on the reduced pittance of 12s. But economy is the order of the day, and if Mr. Childers is likely to be able to show a reduction in the navy estimates we must hold our peace.

ON the 2nd inst. eight of her Majesty's war vessels, viz., the screw sloop "Wasp," 974 tons; the screw sloop "Sharpshooter," 503 tons; the screw frigate "Emerald," 2,913 tons; the screw sloop "Miranda," 1,039 tons; the screw sloop "Niger," 1,072 tons; the paddle-wheel steamship "Thais," 302 tons; and the "Coronation" and "Plym," were offered at public auction, by order of the Lords Commissioners of the Admiralty. The bidding was very spirited, and the prices realised, though not a third of what the vessels originally cost, were, it is stated, more than was anticipated. The following is the result of the sale:—The "Sharpshooter," built at Blackwall in 1846, £1,675. The screw frigate "Emerald," built at Deptford in 1856, £9,000. The "Miranda," built at Sheerness in 1851, £2,550. The "Niger," built at Woolwich in 1846, £4,000. The "Thais," built at Birkenhead in 1856, £775; the "Coronation," £75; and the "Plym," £95. The "Wasp" was bought in at £2,500.

THE Clyde shipbuilding yards have set afloat no fewer than 18 vessels during the month of November. Nine of the launches were at Glasgow, 4 at Greenock, 3 at Dumbarton, 1 at Port Glasgow, and 1 at Rothesay. Nine were steamers, and 9 sailing ships, and, as usual, the large proportion were iron vessels. The total tonnage represented was close on 20,000. The largest vessel of the 18 is the "Scandinavian," an iron screw steamer of about 3,000 tons, built by Messrs. R. Steele and Co., Greenock, for the Allan Montreal Line. Next in size is the "Elbe," a screw steamer of 2,657 tons, built by Mr. John Elder, Govan, for the West India Mail service. The "Apis," an iron screw steamer of 1,200 tons, built by Messrs. Denny, Dumbarton, for the Austrian Lloyd's Service; the "Afrique," a screw steamer of 1,800 tons, built by Messrs. Napier and Sons, Govan, for the Marseilles and Alexandria trade; and the "Shang Tung," a screw steamer of 1,500 tons, built by Messrs. A. and J. Inglis, Glasgow, for the Shanghai Steam Navigation Company, stand next in the list.

THE traffic from the opening of the Suez Canal to the 28th—that is, in eleven days, is reported to have been as follows:—52 vessels arrived from Port Said at Lake Timsah between the 17th and 19th of November, and seven between the 20th and 28th; 51 vessels left Lake Timsah for Suez from the 19th to the 21st, and five from the 22nd to the 28th. The arrivals at Port Said from Suez in the interval between the 18th and 28th were altogether 45. Of these vessels seven were from eastern seas on their way to Europe; nine were from the Mediterranean on their way to the Indies. The total number of vessels that passed through the Canal during the period referred to was 130, the aggregate tonnage of which was 80,000 tons. The telegram from M. de Lesseps with reference to the passage of these vessels was:—"Notwithstanding this extraordinary traffic only six vessels touched the ground slightly; of these four got off without aid, and but two required a little assistance to set them afloat. No loss of cargo, no vessel damaged; neither the bottom nor the sides of the vessel injured.

Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending December 4, was 1,494. Total number since the opening of the Museum, free daily (May 12, 1858), 1,684,665.

A "WORLD'S FAIR" is to be held at Washington in 1871, and subscriptions equal to £240,000 are said to have been already obtained from persons willing to guarantee the required funds, President Grant being among the number for £1,000.

THE annual dinner of the Society of Engineers will take place at the Westminster Palace Hotel, Victoria-street, on Friday, December 17, 1869. Tickets may be obtained at the offices of the Society, 6, Westminster Chambers, S.W., on or before December 13. Members and Associates may introduce friends.

AT the general monthly meeting of the Royal Institution of Great Britain, held on Monday, December 6, Mr. George Busk, F.R.S., in the chair, Mr. George Henderson Gibb, Mr. William Harbottle, Mr. John Henderson, and Mr. Henry Musgrave Musgrave were elected members of the Royal Institution.

THIS evening (Friday) Dr. William Brewer, M.P., will distribute, at the Royal Polytechnic Institution, Regent-street, the certificates and prizes which have been awarded to the students of the evening classes of the above institution. The chair will be taken at eight o'clock, and we hope to see the chairman well supported upon this interesting occasion.

ACCORDING to the latest accounts an extensive area of ground has been taken up for diamond mining on the Cudgegong River, New South Wales, the only locality in that colony where diamond mining has as yet been prosecuted on a large scale. The Australian Diamond Company have provided themselves with a steam-engine for working their gem machinery.

WE learn from "Nature" that Dr. John Davy, brother of Sir Humphrey Davy, has bequeathed to the Royal Society, in fulfilment of an expressed wish of his illustrious brother, a service of plate, presented to Sir Humphrey Davy for the invention of the safety lamp, to be employed in founding a medal to be given annually for the most important discovery in chemistry made in Europe or Anglo-America.

THE number of visitors to the South Kensington Museum during the week ending December 4, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,016; Meyrick and other galleries, 1,203; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,855; Meyrick and other galleries, 84; total, 12,158. Average of corresponding week in former years, 8,226. Total from opening of Museum, 8,981,016.

THE obituary of the "Times" of Saturday, the 27th ult., contained some rare illustrations of prolonged existence, especially so in the case of three ladies and four gentlemen, whose united ages amounted to 602 years, giving an average of exactly 86 years to each of these seven persons. Of the ladies, the eldest had reached the great age of 90 years, the youngest 81; of the opposite sex the oldest was also 90, and the youngest 81 years of age. There were respectively two at 81, one at 85, one at 87, one at 88, and two at 90.

LAST Monday morning, at about 8 o'clock, the roof of the dining-hall of King's College suddenly gave way, and, breaking through the floor, was precipitated into kitchens and offices beneath. The large room which is thus destroyed fronted the river, and the roof formed part of the terrace continued from Somerset House. This roof was supported by iron girders, which have broken in half, and these, together with the brickwork and the superincumbent earth and turf, falling suddenly upon the floor of the dining-hall, the latter was unable to bear the shock, and descended with the rest of the falling mass into the lower storey. Most fortunately no one was injured.

ON the evening of the same day the passenger-shed of the new Caledonian Railway station at the Lothian-road fell with a loud noise. The shed had been completed with the exception of the work to be done by the slaters on the roof, and during the day about 100 men had been employed upon it. When the accident occurred all the workmen had left with the exception of four, who were in one end of the building; but fortunately they escaped uninjured. A horse was caught by some of the beams, but was ultimately rescued without sustaining much damage. The building, which was constructed chiefly of wood, was about 400ft. in length and 90ft. in breadth. The damage is estimated at about £1,200.

THE earthquakes at Gross-Gerau, Germany, continue; down to the evening of the 28th ult. the shocks were frequent, but slight. On the 27th they were rarer than usual, and on the following day only two were observed. At nineteen minutes past ten o'clock in the evening, however, without any previous warning, the ground began to tremble far more violently than it had done since the 22nd ult. Three separate shocks were distinguished, and they lasted together seven or eight seconds. The sensation is described as resembling what would be felt if the whole surface of the earth were sliding down an inclined plane. No other shocks were observed during the night, but this only increased the terror of the inhabitants, who have begun to look on every cessation of these interesting but uncomfortable phenomena as only a sign that an outbreak of more than usual violence is at hand.

ON Wednesday week an extraordinary explosion took place on the premises of Mr. Valentine Blanchard, a well-known authority on English photography. He was engaged in work when some gun cotton and collodion suddenly took fire, exploded with great force, threw Mr. Blanchard into the garden flat on his back, and blew to pieces all the valuable cameras and other appliances of photography, collected and selected after the labour of years. According to the "Standard," Mr. Blanchard was somewhat shaken and had his hand wounded, but his personal injury is as nothing compared with the damage done to his studio and its valuable contents, which he will feel the more acutely as he was about to leave the neighbourhood where the accident took place for the purpose of moving westward. The sympathies of all photographers and of all lovers of the art will be with Mr. Blanchard, whose contributions to the Photographic Exhibition in Conduit-street this year have so materially added to the attractions of that excellent collection of landscapes and portraits.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1503

BUILDINGS AND BUILDING MATERIALS—1495, 1499, 1518, 1534, 1543, 1552, 1558, 1563, 1570

CHEMISTRY AND PHOTOGRAPHY—1493, 1522, 1523, 1540

CULTIVATION OF THE SOIL, including agricultural implements and machines—1518

ELECTRICAL APPARATUS—1560, 1564

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1483, 1500, 1504, 1507, 1509, 1537, 1541, 1545, 1558, 1561

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1511, 1525, 1539, 1550, 1568

FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments, &c.—1482, 1484, 1496, 1501, 1502, 1515, 1525, 1527, 1528, 1531, 1519, 1559, 1666

GENERAL MACHINERY—1488, 1512, 1517, 1569

LIGHTING, HEATING, AND VENTILATING—1551

METALS, including apparatus for their manufacture—1505, 1520, 1524, 1562

MISCELLANEOUS—1486, 1489, 1495, 1498, 1514, 1516, 1521, 1526, 1566

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1481, 1485, 1487, 1491-1492, 1506, 1508, 1519, 1529, 1532, 1533, 1538, 1542, 1544, 1546, 1548, 1554

SHIPS AND BOATS, including their fittings—1447, 1567

STEAM ENGINES—1555

WARFARE—1490, 1510, 1530, 1547

1481 W. FINLEY, Stockport. *Working railway brakes.* Dated May 14, 1869.

The pressure of the buffer rods of the carriages or waggons is made available to apply the brake power, so that when the driver closes the throttle valve, and consequently shuts off the steam, the brakes of the tender become tightened up, and as it were a resistance is thus produced ahead of the train, and, provided these improved "brakes" are fitted to each carriage composing the train, all the carriages throughout the train may have the wheels skidded if the driver considers it necessary to do so.—Patent abandoned.

1482 H. B. BARLOW, Manchester. *Cases for bottles.* (A communication.) Dated May 14, 1869.

This consists in making the cases for bottles and drinking cups of three or more parts screwed or otherwise secured together. The cases may be made of wood or other material. When the case is made of two parts, the lower is made to hold the bottle, and reaches up to about the shoulder of the bottle; the middle part is annular, and passes over the neck of the bottle, and the upper part is made large enough to cover the stopper of the bottle and to contain a drinking cup in an inverted position, the rim of the cup fitting in a circular recess in the upper end of the middle part. India-rubber or other packing is placed in the circular recess, and in the inside of the upper part, to protect the drinking cup when made of glass or porcelain.—Patent completed.

1483 G. F. HENRY, I. A. F. BANG, F. R. C. MONESTIER, and J. P. A. FIGUIER, Paris. *Wool lubrication.* Dated May 14, 1869.

This consists in replacing the oil or matters hitherto made use of for the purpose of lubricating wool by a solution in water, or other suitable menstruum, of any suitable hygroscopic delinquent, salt, or combination of such salts, with which solution the inventors imbibe or lubricate the sheep's or other wool or other similar animal textile fibrous materials intended to be submitted to carding, combing, spinning, or other similar operations, which have been previously deprived of the yolk or adhering natural grease.—Patent completed.

1484 M. WOLFSKY, Pilgrim-street, Ludgate-hill. *Lock for purses.* Dated May 14, 1869.

The mechanism of this lock consists of a plate fixed to the body of the purse; this plate has two grooves formed in it. An upper or movable plate made to slide on or over the first plate. The second plate has on its under side two clips which work in the grooves. A spring is fixed under the first plate, and this acting or pressing on the clips controls its sliding movement.—Patent abandoned.

1485 F. HEDLEY, Richmond. *Horseshoes.* Dated May 14, 1869.

This consists in constructing horseshoes flanged on the outer surface, or so that the inside edge is considerably thicker than the outer edge. The surface of the shoe next the foot may be either perfectly flat or slightly hollowed as preferred. The nail holes are made in the outer or flange portion of the shoe, and consequently the nail head cannot come into actual contact with the hard surface of a road or street until the shoe is nearly worn out.—Patent completed.

1486 J. H. JOHNSON, Lincoln's Inn-fields. *Treatment of beetroot.* (A communication.) Dated May 14, 1869.

The object is to provide a straining or filtering surface for the pressing cylinders used in treating beetroot which shall not be liable to become clogged by the adhering thereto or the accumulation thereon of the solid or tenuous particles of the pulp, the openings being at all times perfectly permeable, whilst the juice itself is allowed to pass through them in a highly pure condition. This result is obtained by the use of a smooth metallic, filtering, or straining surface, that is to say, a surface presenting no rough parts to which the pulp can attach itself.—Patent completed.

1487 C. E. SPOONER, Bron-y-Garth, and G. A. HUDDART, Brynkir, Carnarvonshire. *Railways.* Dated May 14, 1869.

The abutting ends of the rails, whether they be double-headed or formed with a flat base, the inventors propose to clip between two plates suitably shaped to embrace the web and the foot or lower head of the rail, and of such depth that when applied they will extend vertically a sufficient distance below the rail to form a girder or stiff rib, and admit of being secured by spring clamps or otherwise.—Patent completed.

1488 G. T. BOUSFIELD, Loughborough Park, Brixton. *Lifting apparatus.* (A communication.) Dated May 14, 1869.

The lifting apparatus consists of two similar bent levers connected together back to back by a link joined to each lever at a point intermediate of its length. One end of each lifting lever is intended to enter a hole formed for it in the stone or other block. These holes may be cut in an inclined direction so as to recede from each other as they descend into the block, and the ends of the lifting levers which enter them have each a small tooth. The outer ends of the lifting levers stand outwards away from each other, and are connected by a short chain with a ring link in the middle, and the lifting chain is connected with the ring by a hook. When the strain comes on the lifting chain, the teeth on the lifting levers penetrate the outer sides of the lever holes, and prevent the withdrawal of the levers.—Patent completed.

1489 C. H. GARDNER, West Harding-street, E.C., and J. BICKERTON, Oldham. *Lithographic and zincographic printing machines.* Dated May 14, 1869.

A cylinder or roller of the sponge generally known as the india-rubber sponge, or of such like spongy material, is used, to which water or other fluid is supplied either externally or through a perforated hollow tube forming the axis of the roller. A bed, sheet, or slab of india-rubber sponge or similar spongy material is placed in such position with respect to the roller that it is brought by the motion or stroke of the machine into contact with the roller, which is thus allowed to run upon the bed, slab, or sheet. By this contact the moisture of the roller is equalised, and the roller afterwards distributes the moisture to the lithographic stone or zincographic plate.—Patent completed.

1490 I. M. MILBANK, Connecticut, U.S.A. *Cartridges for breechloaders.* Dated May 15, 1869.

The sheet metal case is shown with the base and hollow flange, the latter enabling the breechloading mechanism to draw the case or sheet out of the barrel by means of a retractor taking hold of the flange. The sheet metal cup and the disc are to be soldered into the inside of the shell or case, the solder running into the flange, and also filling the space between the cup or disc and the base caused by countersinking the base for the flange of the priming tube.—Patent completed.

1491 V. R. BATCHELOR, Marylebone. *Giving motion to wheels.* Dated May 15, 1869.

This consists in the application of a triangular or otherwise angled arrangement of rods to the side of each wheel, as for instance, by securing the angle to the pin, so that such rods may stand at such a distance from the side that they may be used as handles for imparting rotation to the wheel or wheels, in order to effect propulsion of the hand carriage.—Patent abandoned.

1492 S. CORBETT, Wellington. *Velocipedes.* Dated May 15, 1869.

In order to enable velocipedes to be converted into two wheel velocipedes or three wheel velocipedes at pleasure, the inventor provides two independent and detachable front axles for the front or driving wheels. One of these axles has a wheel fixed to it at its middle, and is provided with cranks outside the wheel as usual. The other axle he makes much longer than the first mentioned one, and provides each of its ends with a wheel, the cranks on the axle being situate inside the wheels. The inventor so arranges the bearings of each of these axles that one or other of the axles can at pleasure be fixed to the bottom of the fork of the velocipede, at the top of which fork the spindle and cross arm for guiding the velocipede are fixed.—Patent abandoned.

1493 L. A. V. DUBOURG, Leicester-street. *Manufacture of gas.* Dated May 15, 1869.

The apparatus consists of two parts, comprising first the gas generator with a purifier attached thereto, and, second, the carburetter for imparting to the hydrogen gas the requisite amount of carbon to convert it into an illuminating gas. In the generator, the process is carried on automatically, and the gas is produced by the decomposition of water by means of the chemical action of acidulated water on metals. The gas arrives in the carburetter in a nascent state, and by being made to bubble up through the liquid hydrocarbon contained therein takes up the carbon vapour which gives it its illuminating power.—Patent completed.

1494 A petition to extend the time for filing this specification is pending.

1495 W. WILKINSON and M. BOSS, Seymour-street, N.W. *Embossing glass and other surfaces.* Dated May 15, 1869.

This consists, first, in embossing the surface of glass or metal by placing a strip of glass or metal upon a flat movable lid arranged to rise and fall. Upon this lace or other open worked fabric or perforated metal sheets are attached by gum or otherwise. The fabric or metal sheet is then dusted over with powdered resin and other matter. The glass or metal is then removed from the fabric or perforated sheet and placed upon a hot bed or over heated oven, sufficiently to cause the powder to adhere firmly. The glass or metal plate is then removed and fluoric acid poured over its surface. Second, in producing designs upon glass, metal, wood, canvas, &c., by taking a sheet of transfer paper with a loose ground consisting of starch. The surface of the starch is covered with a coating of varnish. The prepared surface of the transfer paper is printed with designs in mineral or vegetable colour. The printed paper is then coated with turpentine or varnish, and then laid on the surface to be ornamented previously coated with adhesive matter. The design is then left on the glass or metal which is heated to evaporate the dampness from it. Third, in preparing the surface of metal plates to receive the enamelling medium by cutting or rolling by means of cut rollers or dies or other contrivances operated upon either in a hot or cold state. The metal plates are also coated with clay as an absorbent by dipping or otherwise. Fourth, in ornamenting the surface of canvas prepared with paint. The print or impression printed on the transfer paper is given a coating of varnish. The canvas is then coated with the same varnish and presented to the surface of the transfer paper. Fifth, in ornamenting wood veneers by embossing by the employment of dies or cut rollers or by means of perforated metal or other plates.—Patent completed.

1496 J. S. JARVIS, Wood-street, Cheapside. *Seamless collar.* Dated May 15, 1869.

This consists in producing by cutting or otherwise a combined collar and tie in one piece and without seams; the portions forming the tie and band are printed or otherwise impressed in one or more colours to imitate silk or other fabric.—Patent abandoned.

1497 T. BERNEY, Bracon Hall, Norfolk. *Mounting armour.* Dated May 15, 1869.

This consists, first, in converting and arranging the armour which by a previous invention is used as a counterweight into and as defensive armour. The inventor prefers, second, to make this defensive covering armour in two parts. The armour is made of any suitable forms and materials, for the purposes required, but by preference of hollow figures presenting rounded forms, so as to tend to cause falling projectiles to glance from off it or them externally.—Patent abandoned.

1498 F. KOHN, Robert-street, Adelphi. *Extracting juice from sugar.* (A communication.) Dated May 17, 1869.

This consists in carrying out the whole process of diffusion in one single vessel or diffuser, in which the sugar extraction is carried on continuously by introducing the slices of cane, beetroot, or other plants through a feeding apparatus at the bottom of the vessel, from which they rise slowly and gradually to the top, while the fresh water is constantly running in at the top of the diffusion vessel, and is drawn off at the bottom as diffusion juice, after having remained in contact with the slices for a sufficient length of time.—Patent completed.

1499 R., J. J., and L. R. BODMER, Notting-hill. *Firegrates.* Dated May 17, 1869.

This consists in the application and use of rollers or cylinders forming a grate surface in lieu of either stationary or movable flat grates, or in combination with either or with both. The rollers, supported in suitable bearings, are ranged parallel to each other, with sufficient space between each two to prevent contact from expansion of the metal.—Patent completed.

1500 R. WILSON, Patricroft, near Manchester. *Spinning and doubling cotton.* Dated May 17, 1869.

The inventor uses a bottom or driving spindle, and a top or flyer and bobbin spindle; on the driving spindle is fixed the wharve or pulley by which the motion is received from the driving drum, or the spindle may be driven in any other ordinary manner; the bottom end of this spindle runs in a footstep in the footstep rail, and the top end runs in a bush in the bolster line. The top end of this spindle is constructed with a clutch socket to receive and turn the top or flyer and bobbin spindle, the bottom end of which is made with suitable projections to fit the clutch socket of the driving spindle, that both may revolve together correctly and yet be easily detached. On the top spindle is fixed the flyer and the top end above the flyer is bored out to form it into a tube through which the roving or yarn passes down to the flyer, and from the flyer to the bobbin or spool, on which it is wound in the ordinary manner by the friction or drag on the lifting rail of the usual construction, on which the bobbin is supported.—Patent completed.

1501 H. DE GARRS, Sheffield. *Gas pendants and chandeliers.* Dated May 17, 1869.

The inventor inserts in the inside of the gas pendants and chandeliers an elastic or spring tube for conveying the gas to the burner, so that the gas pipe retains an unbroken connection, whether the pendant be slid up or down.—Patent abandoned.

1502 H. G. WHITEHEAD, Ecclesall Bierlow, Yorkshire. *Knife cutlery.* Dated May 17, 1869.

The inventor files or punches the springs out of sheet steel of the exact size and shape required according to the pattern of the knives intended to be made instead of punching them larger and then hammering and filing them into shape as is now customary. He then stamps the springs in a boss, which has a recess in it to receive the spring, and prevents the spring from changing its shape while being stamped. He also has dotting points in the impression on the boss to mark the springs for boring, so that the springs are marked for boring in the proper places at the same time that they are stamped. He treats the blade tangs in the same way.—Patent completed.

1503 R. HARLOW, Heaton Norris. *Hot water boilers.* Dated May 17, 1869.

This consists in a cylindrical enclosed casing formed of cast or wrought-iron, copper, or other suitable material tapering or narrowing towards the upper end, in the centre of which the fire is placed. In the body of such casing and concentric with it is suspended a tapered tube or inner casing communicating with the interior of the outer casing and also with the interior of a flat hollow annular dish or flange which surrounds and partially covers the mouth of the outer casing so that as the flame escapes from the neck or narrow mouth of such casing it impinges against the under surface of such dish or flange, and at the same time communicates its heat to the outer casing and tapered tube before mentioned.—Patent abandoned.

1504 D. HITCHEN, Halifax, *Looms.* Dated May 17, 1869.

This consists in substituting in lieu of one of the healds now used a pair of plain, smooth rods or bars of iron or other rigid material for those threads of the warp to pass betwixt which would otherwise have passed through the nails of the heald thus supplanted. The rods are connected at each end to a frame which is capable of sliding up and down in slots affixed to or formed in the loom-frame and operated by the ordinary treadling, tapped, and jack rod or other equivalent and suitable means.—Patent completed.

1505 A. DUNN and A. LIDDELL, White-street, Southwark. *Metal cans.* Dated May 17, 1869.

This consists in constructing metal cans or tins in such a manner as to occupy little space in storage. The first improvement consists in protecting the edges of the vessel from injury by the employment of a twin drum, hoop, or band over the edge of the head or bottom of the tin. Second, in forming the tops or covers for metal cans or tins with a double turned over edge or edges in the manner and for the purpose hereinbefore described. Third, in forming the bottoms for metal cans or tins with double turned over edges in the manner and for the purpose hereinbefore described. Fourth, in the employment of the tops or covers of the bottoms of metal cans or tins with extended and sunken portions.—Patent completed.

1506 C. E. BROOMAN, Fleet-street. *Applying railway brakes.* (A communication.) Dated May 17, 1869.

This consists in fitting to the body or framework of railway carriages, engines, or tenders a series of links or connecting rods for supporting the brakes which are caused to bear upon the ordinary rails or upon an additional rail laid in the space between the ordinary rails. The brakes are actuated by screw or other power either direct or by the intervention of other rods or appliances.—Patent abandoned.

1507 T. WRIGHT and I. FOX, Nottingham. *Bobbin net lace.* Dated May 17, 1869.

The inventors make Ensor net with finings and open work by a stump bar or bars placed above the bottom bars. When they employ one stump bar only the slots formed by the parts of such bar are eight in number, from the front of the machine to the back of the machine. When they employ two stump bars there are five slots in each bar from the front of the machine to the back of the machine.—Patent abandoned.

1508 S. W. CLARK and W. R. SYKES, Clapham. *Railway signal lamps.* Dated May 17, 1869.

The invention mainly consists in placing two or more different coloured shades, curved or flat glasses, in a casing within the lamp, which casing works on a central pivot placed in the lamp casing proper and on the lower part of the same. Upon the upper part of the lamp casing are three or more rollers, upon or against which the internal shade casing revolves or turns, and upon the edge of this casing there are three or more indentations to act as stops to the various glass shades, by means of which they remain secure in proper position. The rollers may be placed in various positions either internally or externally to the lamp casing or casings.—Patent completed.

1509 W. E. NEWTON, Chancery-lane. *Sliver cans.* (A communication.) Dated May 17, 1869.

This consists in making these cans of what is known as "leather board," an article made of leather scraps combined with fibre and other substances.—Patent abandoned.

1510 W. R. LAKE, Southampton-buildings. *Revolvers.* (A communication.) Dated May 17, 1869.

The arm is furnished with an extractor having a flat plate or head, which lies in a recess at the rear of the revolving cylinder in such a position as to form a part of the surface against which the rim of each cartridge shell lies when the same is inserted into its chamber in the cylinder. The extractor also has a tank, which extends through the centre of the revolving cylinder and through a hollow centre pin, upon which the revolving cylinder turns. Where the shank passes through the rear end of the revolving cylinder it is made square, so that it has to turn with the cylinder when the latter is revolved. To the forward end of this extractor is attached a rack by a coupling joint, which allows the extractor to revolve without turning the rack. This latter may be made flat, or may be a circular rod with the teeth cut entirely around it, and for many reasons the latter form is preferable.—Patent completed.

1511 W. R. LAKE, Southampton-buildings. *Drying sugar.* (A communication.) Dated May 17, 1869.

The time for drying sugar loaves in the ordinary manner is from eight to twelve days, but with this improved apparatus the time is reduced to twenty-four hours. This improvement is obtained by producing complete currents of heated air in the loaves themselves.—Patent abandoned.

1512 W. R. LAKE, Southampton-buildings. (A communication.) *Forming screw threads.* Dated May 17, 1869.

This consists in forming such threads by compression between plates having concentric projections upon their faces set at an angle to one another, and revolving upon axes in different planes.—Patent completed.

1513 T. NORRIS, Frome. *Mowing.* Dated May 18, 1869.

The two sides of the frame have each an elbow situate about 16in. from the hind end, and which dips about 20in. At the bottom part of each elbow is a hole through which passes the main axletree and in which it works. Passing through the length of the frame, and about the middle of it, is a part similar to the side of the frame without the elbow, and fastened by means of screws at each end. In this part are two bearings for two minor axle trees, the other bearings of which are in the right-hand side of the frame.—Patent abandoned.

1514 A. TATHAM, Ilkestone. *Barbed needles.* Dated May 18, 1869.

This consists in manufacturing the needles employed in making hosiery and lace which are known as "barbed needles," by stamping them between dies which are acted upon by mechanical means instead of by hand labour, as at present.—Patent abandoned.

1515 T. and J. FAGG, Haymarket. *Overalls.* Dated May 18, 1869.

This consists in the application to garments of a series of elastic tubes of vulcanised india-rubber or other material of a sufficient thickness and strength to resist any ordinary compression, but still of sufficient elasticity to yield freely to the movements of the wearer. These tubes are attached to the interior of the garments by strips, bands, or covering coated with adhesive solution, or they may be attached by other means.—Patent completed.

1516 C. MOSELEY, Manchester. *India-rubber bags.* Dated May 18, 1869.

This consists in making india-rubber bags for felt hats in one piece, and, consequently, without joints.—Patent completed.

1517 J. NORTON, Sheffield. *Cocks.* Dated May 18, 1869.

This ballcock has a chamber in the centre of the cylinder, through which works a cone valve attached to the lever of the ball, which by direct action opens or shuts the valve and prevents it sticking.—Patent abandoned.

1518 J. WATERWORTH, Burnley. *Firegrates.* Dated May 18, 1869.

This consists in combining with ordinary firegrates a movable plate. This plate is placed underneath the grate, and projections or prongs are formed thereon corresponding to certain of the spaces between the bars.—Patent abandoned.

1519 A. M. CLARK, Chancery-lane. *Locomotives.* (A communication.) Dated May 18, 1869.

The inventor makes locomotives as small and as light as possible, the parts being made of steel, and hollow where practicable. These locomotives are relatively of great power, but at the same time save much wear and tear of the road. Two arrangements of driving wheels are provided, the one consisting of large wheels for running on levels and slight inclines, and the other of a system of smaller wheels for ascending steep inclines.—Patent completed.

1520 G. ALLAN, Leadenhall-street. *Securing sheet metal.* Dated May 18, 1869.

In place of fixing the sheet metal or plate direct to the purlins or other objects the inventor secures it to a metal strap passing round or partially round the purlin or other object and arranged either so that both ends of the strap are fixed to the sheet metal or plate by one and the same bolt or bolts or rivets, or so that each end is fixed by a separate bolt or bolts or rivets. The straps or loops, whilst made to grip each purlin tight, are at the same time so shaped as to leave sufficient play between them and the sides of the purlins to allow of the extreme amount of the expansion of the metal covering in one direction, while in the other direction the straps are free to slide upon the purlins.—Patent completed.

1521 F. WALTON, Wolverhampton. *Coal vases.* Dated May 18, 1869.

In constructing coal barges according to this invention the inventor makes them of an outer metallic case and an inner metallic case or frame, the inner case or frame supporting a box in which the coal is placed. This box may either be capable or incapable of removal. The front or one side of the outer case is open, and to the bottom edge thereof the inner case or frame is jointed. By turning the inner case or frame upon its joint it moves in a vertical plane, and can be turned into the outer case, so as to close the vase, or be withdrawn from the outer case so as to open the case.—Patent completed.

1522 J. WOODWARD, Manchester. *Gas water meters.* Dated May 18, 1869.

This consists in the combination of an india-rubber or other elastic or flexible diaphragm with concave or recessed plates or castings having ports and passages in them for the gas or liquid to communicate with each side of the diaphragm, and a slide or other valve or valves to open and shut the communication alternately with the supply and outlet pipe.—Patent abandoned.

1523 W. BENSON, Hexham. *Reducing ores.* Dated May 18, 1869.

This consists in the employment for that purpose of an arrangement of edge runners in place of stamps which have hitherto been employed. The ores or minerals are fed to the runners by means of an upright hollow shaft, the lower portion of which is provided with lateral openings in inclined spouts, over which spouts and through the openings in the shaft the ores or minerals are carried by thin streams of water to the bottom of the pan or saucer, and underneath the edge rolls, by which means the ores or minerals are ground or reduced to a fine thin sludge or slime.—Patent completed.

1524 J. L. CLARK, Westminster, and J. L. BROTHERTON, Wolverhampton. *Iron and steel tubes.* Dated May 18, 1869

The inventor takes a strip of iron or steel, and bends it into a skelp of a suitable form on a bending machine, and then passes it through rolls of suitable section, and with or without a mandrel or core or through draw tongs. for the purpose of producing one, two, or any required number of longitudinal flanges or ribs upon the tube, the two meeting edges being welded in the process, so as to form one of such flanges or ribs.—Patent abandoned.

1525 A. V. NEWTON, Chancery-lane. *Paper hangings.* (A communication.) Dated May 18, 1869.

The object is to produce wall papers that will admit of being washed like painted surfaces without injury thereto. To this end, instead of using distemper colour for the ground of paper hangings, oil colour is applied to the ordinary paper.—Patent abandoned.

1526 E. C. WARBURTON, Bristol. *Registering votes.* Dated May 18, 1869.

The apparatus which the inventor employs when simply votes aye or no require to be recorded consists in two channels formed in a suitable case, which he prefers should form part of the door of a closet in which the voter is enclosed whilst voting; into one or other of these channels, which correspond the one to an affirmative the other to a negative vote, the voter whilst hidden from view deposits the ballot ball, which in running down the passage into which it is introduced touches two triggers, the first as it is moved drives one step forward, the first of a train of counting wheels which give motion to tell-tale hands on dials visible to the voter, and to those exterior to the voting closet. The first triggers of both the ballot ball passages are geared together, so that the tell-tale hands which they actuate indicate the total number of voters using the apparatus. After moving the first trigger the ball rolls on down the passage and touches a second and independent trigger, which also in a similar manner actuates counting wheels indicating on dials the number of motions of the trigger, and, consequently, the number of voters placing the ball in this passage, and as each passage is thus furnished with dials in connection with it, the indications on these dials will show the numbers of the affirmative and negative votes.—Patent completed.

1527 F. JOHNSON and W. HATCHMAN, Little Love-lane. *Umbrellas.* Dated May 18, 1869.

The inventors employ as the thickening material a fibre having the property of resisting the formation of sharp well defined creases; cotton and linen are fibres very suitable for use for the purpose, and by their use in this manner the durability of the umbrella is much increased.—Patent completed.

1528 W. GREEN, Garforth, near Leeds. *Cleaning flower pots.* Dated May 18, 1869.

The apparatus consists of a box or trough (made of wood, metal, or earthenware) holding water. In this box or trough a circular brush is made to revolve on a spindle and working partly in the water. A guard is fitted on one side to prevent splashing, sufficient surface of the brush remaining exposed to effect the object in view.—Patent abandoned.

1529 W. NAYLOR, Mildmay Park. *Railway brakes.* Dated May 18, 1869.

The inventor connects the brake lever with a piston or plunger working in a cylinder containing water or other liquid, which liquid is displaced by the descent of the plunger during the time the brake lever is falling and escapes through a small aperture into an outer chamber surrounding the cylinder, thereby controlling or checking the descent of such lever. In lieu of liquid air may be employed, in which case the outer chamber may be dispensed with. On lifting the brake off again, a valve either in the piston or plunger (or in the bottom of the cylinder) allows the liquid to return again freely into the cylinder.—Patent completed.

1530 J. H. JOHNSON, Lincoln's Inn-fields. *Firearms* (A communication.) Dated May 18, 1869.

One essential feature of this invention consists in the peculiar arrangement of the trigger mechanism, which consists of such a combination of levers that the pressure exerted by the finger on the trigger does not as hitherto involve a powerful friction against the bolt. To obviate this defect, the trigger spring operates on the end of the shorter arm of the trigger, which in its turn transmits its action to the shorter arm of the curved tumbler or lever. This lever is so constructed as never to miss entering to the bottom of the full cock, bent or notch, during the forward movement of the latter, by reason of the end of the tumbler being situate above the axis on which the lever itself works.—Patent completed.

1531 E. TAYLOR, Blackburn. *Washing machine.* Dated May 18, 1869.

The inventor has one or more tubes standing upright, in which the process of washing, churning, or mixing fluids is carried on, and he has a pair of rollers between which the wringing and mangling is carried on. A system of framework supports or fixes the position of the whole. In each tub is an upright dasher made with bars placed either upright, horizontal, or at angle, or composed of flat wings pierced with holes, or a combination of each or any of these. This dasher turns about on a pivot placed at the bottom of the tub, the dasher having a hole in the end for the reception of the pivot; or when it is desired to drive from below a square spike or socket comes through a stuffing box in the bottom of the tub, and which socket or spike the dasher end fits, and which communicates the necessary motion to the dasher. The dasher is supported near the top end by a round or half round bush, which drops into a suitable hole in the framing, which is so arranged that by lifting out the bush the dasher can be removed at pleasure.—Patent completed.

1532 H. LIVESEY and T. COLLINSON, Blackburn. *Velocipedes.* Dated May 18, 1869.

The inventors make the height of the machine adjustable to suit different persons, by making the bearings of the front wheel or that carrying them capable of being moved up or down the legs of the front fork. They make the treadles of gutta-percha, and either bush the hole with metal or not.—Patent abandoned.

1533 J. SAWYER and J. WOODMAN, Islington. *Propelling velocipedes.* Dated May 18, 1869.

This consists in the use of elastic bands, so combined and arranged as to store a portion of the power to each effort of the operator, for the purpose of accelerating and rendering uniform the motion of the vehicle.—Patent abandoned.

1534 R. E. KEEN, Red Lion-court. *Securing panes of glass.* Dated May 18, 1869.

The inventor constructs a metal frame, which is composed of an upper and lower band, united by bars at the corners of the lantern. The panes or sheets of glass are placed upon the outside of these corner bars, and are then secured by metal bars or dips of a V shaped or concavo convex sectional form. These clips extend from the top to the bottom of each pane, and are secured to the upper and lower bands of the frame by means of sockets, screws, pins, or other devices, which will hold them firmly but will also allow them to be readily removed when desired. The bottom of the frame is provided with a fillet to receive the lower edge of the panes of glass, and it is preferred that this fillet should be perforated at the bottom.—Patent completed.

1535 A. VAN WINKLE, Southampton-street. *Securing corks.* (A communication.) Dated May 18, 1869.

This consists of a clip or fastener the ends of which are jointed or secured in eyes or loops formed in a band or ring encircling the neck of the bottle. The clip or fastener is formed with two arms extending up at the sides of the cork, which arms are united by a cross piece designed to rest upon the top of the cork when the same is inserted in the bottle; the inventor prefers to form this clip or fastener of iron wire, which should be coated or covered with tin, lead, or other comparatively non-oxidable metal or material. The top or cross piece is curved or bent in such a manner that the central part projects over and secures the cork when the same is released from the coiling machine.—Patent completed.

1536 W. R. LAKE, Southampton-buildings. *Bottle capsules.* (A communication.) Dated May 18, 1869.

The principle upon which this system is based is the arrangement of the dies in degrees or steps, so that the material, having been subjected to the first pressure in the die at the upper step, falls into the die at the next step, where it is subjected to a second pressure and so on. The number of the steps will be varied according to the number of punches which are to operate in the machine.—Patent completed.

1537 E. H. and A. I. SOLLY, J. F. HALL, and R. BAILEY, Congleton. *Twisting yarn.* Dated May 19, 1869.

Two or more spinning spindles are fixed in a frame, each fitted with an egg-ended fly. The twisted ends from these spindles are collected and passed over a roller, and then guided down to a bobbin on a spindle with a steel fly.—Patent abandoned.

1538 W. MARTIN, Manchester. *Perambulators.* Dated May 19, 1869.

This consists in making the bodies of the perambulators capable of being reversed on their frames when required, for the purpose of preventing the occupants from being inconvenienced by the wind or rain.—Patent completed.

1539 W. R. LAKE, Southampton-buildings. *Obtaining gelatine.* (A communication.) Dated May 19, 1869.

This consists in obtaining pure gelatine or glue stock from such substances as contain glue, forming materials by culminating, and saving the oils and fats therein contained, and is accomplished by means of benzine, naphtha, or other equivalent hydrocarbon.—Patent completed.

1540 G. MARTIN, Dursley. *Generating gases.* Dated May 19, 1869.

The main part of the apparatus is in the form of a cylinder, and is placed either vertically or horizontally, and of such dimensions as may be necessary for the quantity of chemicals which it is designed to employ. The cylindrical vessel may be made of any suitable material, but it is preferred to construct it of iron Through the centre of the cylinder is placed a spindle or shaft, to which are attached arms capable of being adjusted and carrying blades or scrapers, or the arms themselves may be of such form as to act as scrapers.—Patent completed.

1541 P. M'GREGOR, Manchester. *Spinning and doubling.* Dated May 19, 1869.

The inventor proposes to make the copping or ring rails of wrought iron, steel, or cast malleable iron or steel of any form, the thickness of which will not project either above or below the edges of the ring. By this improvement in the construction of the copping or ring rails, when an end breaks the loose end is at liberty to fly, off centrifugally without coming in contact with any portion of the rail, and, therefore, the yarn or thread is not liable to be soiled by the dirt on the rail as heretofore; the peculiar form of the rail also affords great facility in cleaning.—Patent completed.

1542 J. T. LUCAS, Brecknock-road, N.W. *Velocipedes* Dated May 19, 1869.

This consists in adding to the usual pedal action a manual action to be applied to the hind wheels, of which there are two, which manual action also serves as a brake, doing away with the necessity for the usual strap brake.—Patent abandoned.

1543 J. E. and A. DOWSON, Victoria-street. *Foundations for piers.* Dated May 19, 1869.

The inventors propose to apply bearing or base plates beneath the bottom edge of the cylinder, caisson, or tube, such plates being formed with a flat under surface or with one or both surfaces curvilinear or diagonal to the base line. The upper surface, which is passed under the cylinder, caisson, or tube, is oblique or in the form of a wedge or

otherwise, and terminates in a plane surface for the support of the cylinder, caisson, or tube, immediately within which a flange of L iron or other form of iron on the base plate bears against the internal surface of the cylinder, caisson, or tube, and the horizontal portion of the flange is then bolted to a corresponding flange formed on the interior of the cylinder, caisson, or tube, and thus the two are firmly secured together in any other convenient manner.—Patent completed.

1544 A. W. BANKS, Newgate-street. *Velocipedes, &c.* Dated May 19, 1869.
The inventor places the wheels not all in one line, but alternately to the right and left of the fore and aft line of the velocipede.—Patent abandoned.

1545 W. MITCHELL, Waterfoot. *Felted cloth.* Dated May 19, 1869.
The inventor employs three separate carding engines and folders arranged side by side, or otherwise, and each delivering its own sliver into the same "ball cloth" but superposed, that is one over the other, so that the upper one may be of fine wool, the lower one of inferior wool, and the central or middle one of almost any inferior or other fibrous material or mixture of materials capable of being corded.—Patent completed.

1546 D. ROBERGE, New York, U.S.A. *Horseshoes.* Dated May 19, 1869.
The inventor first makes use of a test shoe, made with hind calks, a centre calk, and a short toe calk set towards the back or inner edge of the shoe. He prefers to apply this shoe in the first instance, and in it an injured horse can walk with comparative ease, and frequently go to his labour immediately. By wearing this shoe for a few days it can be ascertained in what position the under side of the hoof should stand to the level surface, because this calk becomes a pivot, and the foot when at rest has no leverage against it to distort any of the joints, muscles, or tendons, and a measurement can be taken and a shoe made therefrom, so that the hoof will bear on the surface in the most comfortable position.—Patent completed.

1547 G. V. FOSBERY, Cowley. *Breech-loading firearms.* Dated May 19, 1869.
The block slides in vertical grooves in the breech chamber, and is raised or depressed therein by a lever pivoted at the rear of the chamber. The firing pin extends through the block and lever. The block and lever are depressed to open the breech, and the empty cartridge shell is ejected and the piece cocked by one movement of a sliding extractor bar, which is arranged at the side of the breech chamber. A stud on this sliding bar works in an inclined slot or passage in the lever, and acts as a cam to raise or depress the same. The main spring is attached to the under side of the block lever. The cork is provided with a hammer, which, by means of an ordinary trigger, is caused to drive forward the firing pin. The block lever is sometimes provided with a plate, which is caused by the extractor bar to start the pin from the base of the shell.—Patent completed.

1548 F. ZYSEL and O. BURDETT, Birmingham. *Velocipedes.* Dated May 19, 1869.
This consists, first, in cranking the axles of both the fore wheel and hind wheel or wheels, by which means the motive power can be applied on a tread connected to the fore and hind cranks, both the fore and hind wheel or wheels being thereby made traction wheel. Second, in making wheels for velocipedes by casting them of suitable metal in two parts, by which strength and lightness will be obtained.—Patent abandoned.

1549 W. M'ADAM, Glasgow. *Manufacture of pottery.* Dated May 19, 1869.
The mechanism consists of a horizontally revolving table having an intermittent action, so that it stops at certain intervals and allows time for the several operations of the manufacture. The table is arranged to receive five or any other required number of moulds in order to admit of the required number of motions to go on simultaneously.—Patent completed.

1550 W. M. MOORE, Balscaddin Howth, Dublin. *Caps for bottles.* Dated May 19, 1869.
The inventor constructs a hollow cap of india-rubber or other elastic material, which, upon being pressed or sprung on to or over the neck of a bottle, effectually closes the opening and prevents the contents of the bottle from escaping the lip or lower edge of the cap by springing into the hollow in the exterior of the bottle neck.—Patent abandoned.

1551 J. LANGHAM, Leicester. *Ash pans.* Dated May 19, 1869.
The inventor employs a movable ash pan, such as now commonly used, to receive the ashes from a firegrate, and within this ash pan and fitting closely to the sides thereof, he places a sifter or riddle with a perforated or open work bottom, which is kept a slight distance above the bottom of the ash pan to allow the ashes which pass through the riddle to accumulate in the ash pan beneath it.—Patent completed.

1552 W. F. FULLER, Bank, Worthing. *Securing safe doors.* Dated May 19, 1869.
The inventor makes the stem of the bolt with a screw thread upon it, so that by turning the screw stem by a hand wheel upon its upper end the bolt may readily and with very little exertion be raised and lowered or moved to and fro. With the upper end of the stem of the bolt the inventor also combines a lock, by which, when the bolt is fastening the door of the safe or strong room, the stem of the bolt may be locked and prevented from turning.—Patent abandoned.

1553 J. BOWMAN, Peasholme Green, York. *Window blind fittings.* Dated May 19, 1869.
The inventor mounts a ratchet wheel on the stud or pivot, on which the roller turns as the blind is drawn up; a pawl, carried by the roller, then runs over the teeth of the ratchet, and when the blind is raised to the height required, by dropping between the teeth of the wheel prevents the blind running back. This part has a disc at its end which is nipped and held between two levers jointed to the blind frame. These levers are at their lower ends connected together by a screw, and by turning this screw the levers can be made to nip the disc on the stud or pivot with any required amount of pressure.—Patent abandoned.

1554 A. J. DUDGEON, Millwall. *Propelling vessels.* Dated May 19, 1869.
The inventor employs for this purpose turbines mounted on horizontal axes, and driven by steam engines or other suitable motive power. The turbines draw in water by passages through the bottom or sides of the ship, and discharge it horizontally through curved passages terminating in orifices projecting from the side of the ship.—Patent abandoned.

1555 1556 Petitions to extend the time for filing these specifications are pending.

1557 Z. E. COFFIN, Newton Center, U.S.A. *Stop cock.* Dated May 20, 1869.
The case of the cock is connected to the pipe or pipes by couplings, bolts, or otherwise, and the case contains two flat valve seats facing each other, and standing at an inclination to each other. Between these seats the valves work, and they are slidden off the seats to open the cock, or forced down between the inclined seats to close the same.—Patent completed.

1558 C. C. PARKER, Brooklyn, U.S.A. *Cord tighteners.* Dated May 20, 1869.
This consists in a cord tightener in which the grooved pulley is fitted on a slide with a helical spring that yields as the cord expands or contracts, and there is no possibility of the slide becoming wedged or obstructed because this slide is L-shaped, one arm carrying the pulley and the other arm setting within the helical spring, so that the helical spring intervenes between the slide and the case and prevents the parts sticking.—Patent completed.

1559 G. PERKIN, Derby. *Cup and ball castor.* Dated May 20, 1869.
The improvement in the ball-bearing cup consists in forming it with an internal and circular step, the nosing or projecting edge of which, slightly rounded, rests upon the ball and forms its bearing. The inventor makes the diameter of this circular bearing step about two thirds (more or less) of that of the diameter of the ball or globe which forms the runner of the castor.—Patent completed.

1560 A. A. ROSSIGNOL, Paris. *Electric clocks.* Dated May 20, 1869.
A spiral spring of suitable strength is fixed at one end on an arbor of the mechanism to be moved, and at the other end on a ratchet wheel movable on this arbor. A stop spring holds the wheel in the position required for giving the necessary tension to the spring. This spring draws round the arbor and the centre wheel which turns the second wheel by means of a pinion. The second wheel is provided with pins serving to raise a light copper rod or spring for shutting off the current from a battery passing through the electro-magnet.—Patent completed.

1561 J. REID, Glasgow. *Communicating in looms.* Dated May 20, 1869.
This consists in putting a toothed wheel on to an axle of each carriage, and near this toothed wheel another similar wheel is situated having a crank attached to it. The second toothed wheel is provided with means such as a clutch or some analogous contrivance by which it may be put into gear with the toothed wheel on the axle; wires, ropes, or chains pass from the connections of the second toothed wheel to the interior of each compartment of the carriage, and these are again connected to handles in connection with indicating dials.—Patent abandoned.

1562 J. M'MILLAN, Dumbarton, and J. M'GREGOR, Glasgow. *Iron and steel preserving.* Dated May 20, 1869.
This consists in covering the iron or steel or structures composed thereof with sulphur. In applying the sulphur it is melted, and on being brought into contact with the cold iron or steel it is suddenly chilled and sets into a hard thin layer of sulphur covering them.—Patent abandoned.

1563 M. JARVIS, Mansell-street, E., and E. MILLWARD, Skinner-street, Somers Town. *Lock spindles and door knobs.* Dated May 20, 1869.
This consists in the employment of a sliding plate or catch working within a suitable opening formed to receive it in the bushings of the door knob, such plate or catch working in connection with notches or recesses formed on one or more sides of the lock spindle.—Patent completed.

1564 T. HERBERT and J. C. FOWLER, Riverhall-street. *Electric signals.* Dated May 20, 1869.
The inventors first form a hole in the desired position large enough to admit of the outer tubular contact piece being readily pushed in without hammering. This tubular contact piece is provided with lugs or projections on the outer end thereof to ensure its being kept in proper position, and it is insulated from the metal washer or disc by means of a disc of indiarubber or other suitable material interposed between the two.—Patent completed.

1565 H. E. NEWTON, Chancery-lane. *Coffee mill.* (A communication.) Dated May 20, 1869.
The bowl is provided with a cover which is fastened to it by clamps adjusted to handles, the clamps having grooves for the reception of the handles, thus forming a kind of bayonet joint which is fastened by slightly turning the cover round. Under the cover is fixed a hopper having at its bottom a box or casing for the grinding block. The axle of this block is supported by a box below and by a collar above the cover.—Patent abandoned.

1566 J. P. NOLAN, Shoeburyness. *Distance measuring.* Dated May 20, 1869.
The instruments and fittings consist of two metal Y's and V's to each gun fitted with the instruments, consisting of a pair of angle finders, of a roller or mechanical calculator, and of a measuring tape wound round a spinning rack. The best way of fitting the Y's and V's is to make the stem of one of them the same shape as the tangent sight bar of a gun so that it can be slipped into the place of an ordinary tangent sight at will, and be fastened permanently by screws or otherwise. A second Y or V is attached (permanently if required) about 14in. in front of the other to the gun.—Patent completed.

1567 W. R. LAKE, Southampton-buildings. *Boat detaching apparatus.* (A communication.) Dated May 20, 1869.
Two corresponding metallic plates are connected together parallel with each other by an intervening block of like material, and having proper spaces for the insertion of three adjustable parts. One of the parts is curved at one end and forms the hook proper, its other end being articulated to and between the lower ends of the connected plates so as to swing freely below the connecting block of the plates.—Patent completed.

1568 G. JOHNSTON, San Francisco. *Distilling.* Dated May 20, 1869.
This relates to an arrangement of the furnace with two discharge flues, one of which connects with the space beneath the alembic or retort, and the other with the chimney, so that by means of a slide or damper the current of heat may be directed into either passage at pleasure, and thus obviate the necessity for withdrawing the fires during the process of charging and discharging the still. The retort has a series of horizontal diaphragms or partitions commencing near the bottom and reaching to the top, which separate it into chambers, the lower ones being connected by means of hollow return columns, the next ones having distributors so contrived as to thoroughly pass the hot vapours through the liquid contained within the chambers, while the upper chamber of all contains a number of coils of pipe, or other device, through which the vapours pass, and thus heat a charge of alcoholic liquid contained within the chamber.—Patent completed.

1569 J. G. TONGUE, Southampton-buildings, Chancery-lane. *Cutting machines.* (A communicaton.) Dated May 21, 1869.
Two simultaneous movements are employed, one for the advancement or progression (more or less slow) of the wood or other material to be cut, the other for the perpendicular or oblique transverse movement of the blades or knives; the speed of this movement depends on the nature of the woods or substances to be cut.—Patent completed.

1570 S. JACKSON, Bradford. *Window shutters.* Dated May 21, 1869.
This consists in constructing window shutters of laths or narrow strips of wood or other suitable material arranged horizontally and hinged together, the joints being on alternate sides so as to allow them to fold in a zigzag manner one upon another. A box or receptacle is also formed or provided under the window bottom betwixt the masonry and the lining of suitable dimensions to receive and contain the shutters when folded.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated November 30, 1869.

3459 W. H. Shaw and J. M. Audus, Elland, near Halifax, Yorkshire. Improved machinery or apparatus for dressing millstones.

3460 J., J., and W. H. Wood, Hollinwood, Lancashire. Improvements in ventilating hats or other coverings for the head.

3461 C. H. Hudson, New York, U.S.A. Cots or bedsteads, and guards to be attached thereto, which latter may also be used in other positions.

3462 E. T. Hughes, Chancery-lane. Improvements in the manufacture of elliptic springs, and in apparatus employed therein.

3463 A. W. Pocock, Claverton-street, Pimlico. Improvements in meters or apparatus for measuring water and other liquids.

3464 W. H. Willis, Long-acre. A new or improved apparatus for registering or indicating the points of games, also applicable to calenders and other similar useful purposes.

3465 B. Acton and J. Mustard, Stroud, Gloucestershire. Improvements in machinery for feeding carding engines.

3466 W. Avery, Redditch, Worcestershire. Improvements in umbrellas and parasols.

3467 E. Ensor, jun., Woodville, near Burton-on-Trent, Staffordshire. Improvements in kilns for burning pottery and salt glaze ware, applicable also to the burning of bricks and to the annealing of iron.

3468 A. V. Newton, Chancery-lane. Improved apparatus for converting reciprocating motion into rotary motion.

3469 R. Milburn and T. Browning, Church-lane, Whitechapel. Improvements in drying machines.

3470 J. F. Crease, Eastney, Southampton. Improvements in the construction of tank filters, and in the conversion of tanks into filters.

3471 R. Hornsby and J. E. Phillips, Spittlegate Iron Works, Grantham, Lincolnshire. Improvements in reaping and mowing machines, and in apparatus for sharpening the knives of such machines.

Dated December 1, 1869.

3472 W. Spence, Quality-court, Chancery-lane. Improvements in the manufacture of soda crystals.

3473 T. G. Green, Church Gresley Pottery, Derbyshire. Improved machinery or appliances for use in the manufacture of articles of earthenware and chinaware.

3474 J. Forbes, Perthshire. Improvements in desiccating malt, grain, and other similar substances, and in means employed therefor.

3475 J. James, Princes-street, Stamford-street. Improvements in apparatus for stamping or marking letters, packets, or other articles.

3476 A. C. Henderson, Charing Cross. Improvements in apparatus for shearing or clipping animals, the said apparatus being also applicable to shaving skins.

3477 J. T. Griffin, Upper Thames-street, City. Improvements in preparing, treating, and curing sponge to render it elastic and suitable for use as a stuffing for beds, cushions, seats, and other similar articles.

3478 W. Bennett, Aston, near Birmingham, and J. Currall, Birmingham. Improvements in kitchen ranges and fireplaces or stoves for cooking and heating, and in apparatus connected therewith.

3479 F. N. Target, Colyton, Devonshire. Improvements in waterclosets.

3480 J. Peirce, Stamford-street, Lambeth. An improved compound machine for cutting tenons and mortises and sawing wood.

3481 W. Richards, Birmingham. Improvements in firearms and cartridges.

3482 H. C. Ash, Oxford-street. Improvements in the manufacture of churns.

3483 R. Robey and J. Richardson, Lincoln. Improvements in steam engine governors and apparatus connected therewith.

3484 R. N. Slight and W. F. Denholm, Chirnside Bridge, Berwickshire. Improvements in the straining of paper pulp, and in the machinery, mechanism, or apparatus therefor or connected therewith.

3485 G. Hammer, Griffin-court, Mayfair. Improvements in cork-cutting machines.

Dated December 2, 1869.

3486 H. C. Pennell, Woodlands, Weybridge. Improvements in rifles, fowling pieces, and small arms.

3487 J. B. Wilson, J. Higginbottom, and I. Royse, Stockport, Cheshire. Improvements in bowls or rollers used in calendering and other pressing or squeezing machinery.
3488 A. Mitchell, Leith, Mid Lothian. Improvements in caissons or apparatus to facilitate the building of bridge piers and similar structures under water.
3489 F. C. Webb, Northumberland-terrace, Regent's Park-road. Improvements in the manufacture of submarine telegraphic cables, and in the machinery employed in such manufacture.
3490 A. P. Stirling, Peebles, North Britain. An improved spittoon, specially applicable to railway carriages.
3491 J. H. Johnson, Lincoln's Inn-fields. Improvements in spring mattresses.
3492 H. H. Mayden, Mansfield, Nottinghamshire. Improvements in machinery or apparatus for spinning tobacco.
3493 J. W. and E. Whittaker, Carlisle Villa, Moses Gate, near Bolton-le-Moors, Lancashire. Improvements in steam boiler furnaces and flues.
3494 P. A. S. Langlois and L. S. Tomassin, Boulevart St. Martin, Paris. Improvements in the manufacture of sulphuric acid.
3495 E. Field, Chandos Chambers, Adelphi, Westminster. Improvements in valves for steam fire engines and other pumps.

Dated December 3 ,1869.

3496 W. Tatham, Rochdale, Lancashire. Improvements in machinery for opening and breaking hard waste rags of cotton, woollen, flax, or silk, and for scutching and carding cotton, wool, and other fibrous substances.
3497 J. Smith, Carshalton, and T. Eastwood, Lambeth. Improvements in working and reversing the valves of steam and other engines.
3498 J. M. Macintosh, Grosvenor-road, Pimlico. Improvements in apparatus for taking up, carrying, and laying sheets of paper delivered by a paper cutting or other machine.
3499 J. C. Wilson, Martin's-lane, Cannon-street, City. An improved revolving engine and pump, applicable as a fluid meter.
3500 W. M'Lean, Glasgow. Improvements in printing, lithographing, and zincographing, and in the means or apparatus employed therefor.
3501 J. Jeavons, Atlas Works, Sheffield. Improvements in the manipulation and manufacture of armour plates and other heavy forms of malleable iron.
3502 E. V. Neale, Lincoln's Inn. An improved method of fastening objects capable of rotating on hinge joints.
3503 T. W. Tobin, Royal Polytechnic Institution, Regent-street. A new or improved electric telegraph apparatus.
3504 T. R. Crampton, Great George-street, Westminster. Improvements in burning powdered fuel and in furnaces and apparatus for burning powdered fuel, also in adapting such furnaces for the melting and working of glass, iron, steel, and other material, and to heating steam boilers.
3505 H. Larkin, Torriano Cottages, Leighton-road, and W. White, Thurlow-road, Hampstead. Improvements in the production of potassium, sodium, and zinc.
3506 J. and S. Loebl, Aldermanbury, City. Improvements in fastenings and locks for bags and other like articles.

Dated December 4, 1868.

3507 J. Boyd, Glasgow. Improvements in machinery for winding yarn or thread upon conical surfaces.
3508 C. W. Petersen, City-road. Improvements in the construction of lifeboats and other floating bodies, and in the mode of propelling and ventilating the same, and in steam boilers to be used therewith.
3509 J. F. Kent, Thornton Heath. An improved mortising, tenoning, and sawing machine.
3510 H. M. Nicholls, Arundel-street, Strand. Improvements in apparatus for cutting continuous paper into sheets, and in piling or disposing of the same when cut.
3511 S. Alley, Glasgow. Improvements in breakwaters.
3512 J. Knowles, Burnley, Lancashire. Improvements in rotary engines to be worked by steam, air, water, or other fluid, which improvements are also applicable for raising fluids.
3513 J. Walker, Clayton-le-Moors, Lancashire. Improved material to be employed in the manufacture of blankets known as washing blankets, as used by calico printers, and for other purposes requiring a waterproof material having an absorbent surface.
3514 H. Alexandre, Rue St. Appoline, Paris. Improvements in organs and similar musical instruments.
3515 W. Brookes, Chancery-lane. Improvements in fluid lenses.
3516 T. Magguire, South-terrace, Inchicore, Dublin. Improvements in the packing glands of steam and other engines.
3517 A. Ripley, West-square, St. George's-road, Southwark, and J. Wormald, Blackfriars-road, Southwark. A new or improved pipe wrench.
3518 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in harness for draught animals.
3519 T. Clark, Cheapside, City. Improvements in the covers of umbrellas and parasols.
3520 S. Chatwood and J. Crompton, Bolton-le-Moors, Lancashire. An improved self-acting escape valve for drawing off the condensed fluids from steam engines, pipes, and other steam vessels.

Dated December 6, 1869.

3521 J. L. Booth, Rochester, New York, U.S.A. Improvements in the manufacture of rails for railroads.
3523 T. Prideaux, Sheffield. Improvements in purifying and calcining gas and soap limes and other chemical refuse of lime which has been used in the manufacture of such articles.
3523 W. Shanks, Johnstone, Renfrewshire. Improvements in machinery for forging horseshoes and similar articles.
3524 H. H. Murdoch, Staple Inn. Improvements in, and apparatus for, forming and joining the ends of iron and other tubes or pipes.
3525 J. B. Spence, Manchester. Improvements in the manufacture of alum.
3526 J. B. Spence, Manchester. Improvement in the production of a substance to be used in the manufacture of paper in a similar manner to alum or sulphate of alumina, which substance is also applicable as a mordant in calico printing, and to other manufacturing purposes in which alum or sulphate of alumina is employed.
3527 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for hulling grain or seed.
3528 W. Geeves, Thornhill-square, Barnsbury. Improvements in the manufacture of capsules or packages for containing tea and other like articles, and in apparatus mployed in such manufacture.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," December 7, 1869.

2225 W. Warren
2241 J. H. Johnson
2244 S. Cotton
2277 D. T. Bostel
2281 W. A. Lyttle
2286 A. Burdess
2295 J. S. Kipping
2298 G. Allibon
2310 J. Beckett
2315 L. W. Wright
2325 W. E. Gedge
2331 T. Livesey and T. Abbott
2335 G. S. Hazlehurst
2341 J. Elce and R. Bond
2360 G. Nickerson
2377 J. H. Johnson
2385 T. Hancox
2387 E. T. Hughes
2398 C. D. Watson
2454 B. Hunt
2492 L. B. Fortin and J. Ferrabee
2557 R. H. Herriott and C. and W. A. Plumbe
2603 G. Henley
2692 T. Restell
2777 B. Hunt
2753 W. J. Cunningham and A. P. M'Carthy
2852 E. A. A. Hugo
2879 J. B. Bradshaw
2954 A. V. Newton
2961 T. Cope, J. Hignett, and G. Lauder
3017 H. M. Marsden
3125 W. Brookes
3134 J. James
3165 E. Ford
3203 E. Edmonds
3219 J. C. Heywood
3226 W. R. Lake
3239 H. Lee
3250 W. R. Lake
3308 J. Oppenheimer
3320 G. R. Sweetser and G. Wadman
3322 J. Woodward
3332 J. Dockray
3351 T. Aitken
3359 J. H. Fraser
3361 Sir J. M'Neill
3363 J. Burroughs
3375 E. E. Allen
3379 S. G. Arnold
3456 W. R. Lake

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed within twenty-one days from the date of the "Gazette" in which the notice appears by leaving at the Commissioners' office, particulars in writing of the objection to the application

LIST OF SEALED PATENTS.

Sealed December 3, 1869.

1724 J. Edge
1737 T. Wilkins and W. Fisk
1750 W. B. Leachman
1758 F. Heckner
1759 W. Sellers
1760 G. Fenner
1764 C. E. de Loriere
1782 A. St. C. Radisson
1802 E. T. Hughes
1812 J. H. Brown
1814 W. R. Lake

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department. 166, Fleet-street, London, E.C. ,to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, DECEMBER 17, 1869.

THE AUSTRIAN TORPEDO.

THE most recent addition to the history of the Torpedo question and its practical development is furnished by some experiments which have lately been carried out in Austria with a submarine self-propelling torpedo. Our pages bear ample testimony to the ingenuity which has been for several years past expended upon instruments of the torpedo class for defence against the attack of war vessels. During the Russian war Cronstadt was defended by this class of weapon sunk in the channels of approach and ready to be fired by electricity. Later on, during the American war, similar means were resorted to for coast and harbour defence. In the present instance we have a powerful agent of destruction, which may be seen at the little port of Fiume in the Adriatic. We are not able to place a detailed description of this machine before our readers, inasmuch as the important parts are kept secret by the inventor, who prefers to do this rather than to patent his principle, and thereby expose its peculiarity. We can, however, furnish a general idea of its external form and what it is capable of doing, having been favoured with these particulars by a correspondent—Mr. Andrew Leighton, of Liverpool—who has recently returned from Fiume, where he witnessed the experiments with the torpedo. In appearance this formidable weapon is like a fish, approximating to the form of the sword-fish. But, besides a projecting snout, it possesses a vertical and two lateral projections, all of which are triggers, and any one of which impinging upon an object with sufficient force explodes the machine. It has therefore, when in operation, four chances of effecting its purpose—by the direct stroke in front, or the oblique from either side, or the hit above in passing under the bottom of any object against which it may be launched. It can be charged with any explosive material—gunpowder, gun-cotton, dynamite, or nitroglycerine, and the explosion can be of such force as to drive a hole into the strongest ironclad sufficient to sink her at once.

The most prominent and important feature in the invention is the means by which it can be propelled at any required depth below the surface of the water. When the depth at which it is to proceed is fixed upon it can be driven in a horizontal plane at that depth, towards any mark, at a maximum speed of ten knots an hour. While Mr. Leighton was at Fiume, a commission from the United States, consisting of Admiral Radford and two officers of the United States frigate "Franklin," was engaged in investigating its nature and powers. The experiments had just closed when Mr. Leighton reached the scene, but the inventor subsequently showed the torpedo in operation. It was set off from the side of a boat, and after attaining a depth of some six or eight feet from the surface, it kept as nearly as could be judged the same level, and made three circuits, of from 100 to 150 yards each, round the boat, coming to the surface when its propelling power—compressed air—was exhausted. The water at Fiume is very deep and remarkably clear, so that the monster fish was perfectly defined at the depth stated. Its course could also be seen by the bubbles of air coming to the surface in its wake at a considerable distance behind it. The invention of this torpedo is due to Mr. Robert Whitehead, an English engineer resident at Fiume, and chief of an engineering establishment there. The idea was first started by Captain Luppis, a retired officer of the Austrian navy, who suggested to Mr. Whitehead the desirability of a floating and running torpedo, the forepart to be filled with explosive material and the after-part with the motive power, which latter was to be steam. But, on giving his attention to it, Mr. Whitehead soon saw that Captain Luppis's notions were wholly impracticable; that a surface-floating body would never answer the purpose; and that fire or steam in close proximity to explosive material would be so dangerous that this idea of the gallant captain had to be abandoned as worse than useless. He, therefore, set to work upon an idea altogether his own, which was to form a fish instead of a steamboat; and, after innumerable mistakes, failures, and disappointments, his perseverance was at length rewarded by the triumphant success already indicated. Thus to English, and not to Austrian, mechanical genius—as has been incorrectly stated in some quarters—belongs the honour of this latest achievement in the art of defensive warfare, which, if it does not render other coast defences needless, must at least be acknowledged as a potent auxiliary for maintaining our island home invulnerable; that is, if our government have had the wisdom to possess themselves of its secret. It is impossible for anyone who has seen this torpedo in operation to hesitate in his judgment as to its superiority over anything of the kind hitherto invented; and it is difficult to estimate the extent to which this single invention will modify the arts of attack and defence by sea.

PERMANENT PHOTOGRAPHS IN CARBON.

SINCE Mr. J. W. Swan, of Newcastle-upon-Tyne, first published a process in carbon which could be practically worked for the production of permanent photographs, several improvements have been made, and at the present time such pictures are readily purchasable in London at very moderate rates. All the carbon processes have been patented, and they have been bought up by the Autotype Company. The ordinary photographs upon albumenised paper are, as we have often pointed out, sure to fade after a greater or less lapse of time, and are therefore of no historical value; but where the shadows of a picture consist of carbon pigments, the imperishability of this most durable of all colouring substances necessarily ensures the permanence of the pictures. Carbon was the base of the most imperishable of the inks used by the monks of old, and is the cause of the durability of so many ancient black-letter manuscripts.

The principle of the carbon processes has already been published in these columns, but it is best to briefly state it once more, in order to more clearly explain the nature of the improvements recently made in the manipulations. Gelatine, mixed with solution of bichromate of potash or ammonia, and dried, is soluble again in warm water provided light has not been allowed to act upon the substance throughout the operations. Light, however, makes it insoluble in warm water, and the longer it is exposed to light the deeper does the action penetrate, so that a great thickness of it may in time be thus made insoluble. These facts were originally discovered by Mr. Mungo Ponton, F.R.S.E., of Clifton. In carbon processes, Indian ink or other colouring matter is added to the gelatine and bichromate of potash; a film of the dark mixture is made, dried, and exposed to light under a negative. Next, it is mounted on white paper, and subjected to the action of warm water. Where the light has not acted, the carbon tissue is all dissolved away, leaving the white paper to form the lights of the picture. Where the light has acted vigorously, a dark black deposit is left to form the darkest shadows of the picture, and where the light has acted only to a moderate extent thinner deposits of colouring matter remain behind to form the half-tones.

In the old carbon process, a glass plate was coated with collodion and dried by heat; the warm gelatine pigment was then poured on in a thick pool, the plate was next placed accurately in a horizontal position, and the whole left for several hours to dry in the dark. When dry, one corner of the film was lifted by the aid of a penknife, and the whole of it then gently peeled off the plate by pulling it steadily with the fingers. In this state the surface which had been nearest to the glass resembled exquisitely polished patent leather. This polished surface was placed next the varnished side of the negative, exposed to light, and mounted upon paper. It was absolutely necessary that the polished surface should be the one fixed in contact with the paper, because the light had acted from that surface to different depths, rarely penetrating the whole film. Therefore, if the other surface were attached to the paper, the whole of the delicate shadows would be lost in the warm water, simply because they would have nothing to attach them to the paper when the pigment behind them dissolved off. This double transfer from glass to paper was the most troublesome part of the operations, and the pigment could only be satisfactorily attached to the paper by means of a solution of benzole in indiarubber, and pressure between rollers. By the present method, this troublesome work is avoided, Mr. J. R. Johnson having found out how to overcome the difficulty.

The process at present used by the Autotype Company is as follows:—The pigment without any bichromate is made as already described, a little sugar, however, being added to make the tissue more pliable when dried. A little blue or red colouring matter is also added, to improve the tone of the colour of the Indian ink. A large vessel is filled with the gelatine pigment, and kept steadily at a temperature just high enough to prevent it from solidifying. A great length of paper is then joined at its two ends, so as to form an endless band, which travels loosely and slowly round and round upon rollers. At its centre this band dips into the gelatine pigment, which partially dries upon the paper before it passes into the liquid pigment again. In this way the paper band receives successive thin coatings of the pigment, until the desired thickness is attained. It is then dried and cut up into sheets, which as yet are insensitive to the action of light, because they contain no bichromate salts.

The paper is sensitized a few hours before it is wanted for use by floating it for two minutes upon a solution containing 22 grains of bichromate of potash to each fluid ounce of water. This must, of course, be done by yellow, orange, or red light. The tissue is then dried in the dark, after which it is exposed under the negative. The eye is no guide to printing by the carbon process, so the right time of exposure for every separate negative is ascertained by means of a few experimental trials and a photometer; this point is the worst and most troublesome portion of the carbon process, as it stands at present. Next the exposed surface is wetted, and without any cementing substance it will adhere to any surface which is impermeable to water. The gelatine, not being saturated, rapidly absorbs the superfluous moisture after it is thus placed in contact with its support. The whole is then dipped in warm water, where the superfluous pigment dissolves away and the picture shows as a transparency, supposing the support chosen be a sheet of glass. When paper is used it is necessary that it should be impermeable to water, and this is effected by means of albumen coagulated by alcohol.

To make an opalotype the exposed tissue

is immersed in water for a few minutes, and then raised from the liquid by means of a plate of opal glass placed beneath. Next, a pad of blotting paper is laid upon the tissue, and all air bubbles between the tissue and the glass are carefully pressed out. After the lapse of some little time, to permit partial drying, the development is effected at a temperature of about 100deg. Fah. and the picture is finished. When it is desired to transfer such pictures from glass to paper the glass is rubbed over, in the first instance, with a solution of stearine in weak methylated alcohol, which is then polished off again, but it leaves an imperceptible film behind, which prevents the pigment from adhering too firmly to the glass. After the development is finished a sheet of paper coated with transparent gelatine is wetted and pressed into contact with the glass, care being taken to exclude air bubbles; then the whole is allowed to dry, after which the paper may be peeled from the glass, bringing the picture with it entire and uninjured. Sometimes the exposed carbon tissue is mounted directly upon paper which has been rendered impermeable to water by some process not yet made public; it is then developed, and the picture is finished. The paper is probably treated with a solution of some resinous substance in weak methylated spirit.

Such is the carbon process, as it stands at present, and it exhibits many simplifications not to be found in the original process, which we published several years ago. Considering the large number of pictures of English scenes and English celebrities which are taken by photography every year, it is a pity that records of so much historical value should not be printed in a permanent manner. Negatives were taken of the site of Holborn Viaduct before its erection and this instance alone shows the desirability of permanently printing a scene from "Old" London which mortal eye will never see again, except upon paper. Silver prints from these negatives were on view at the recent exhibition of the London Photographic Society in Conduit-street. As for silver pictures upon albumenised paper, they fade rapidly away, so it may be more truly said of photographers than other people—"They die, and their works do follow them."

THE SMITHFIELD CLUB SHOW.

IN resuming our notice of the Smithfield Club Show, we will first look at the stand of Messrs. Richard Garrett and Sons, of the Leiston Works, Suffolk. This firm exhibited a great variety of seed drills, horse hoes, manure distributors, field rollers, and a number of useful implements of their usual excellent make. But we would call special attention to their self-moving agricultural engines, which were designed by this enterprising firm to meet a want which had often been much felt. This want was a light self-moving engine capable of being easily transported from farm to farm. The advantages of Messrs. Garrett's self-moving engine are that it will draw a thrashing machine and straw elevator with ease, and pass over soft land and places where it would be exceedingly difficult to take machinery by horses. This engine is but a few hundredweights heavier than a portable engine of the same power. This firm also exhibited Hayes' straw elevator, and a very well-arranged continuous iron framed stone grinding mill, with 48-inch French Burr stones. These mills are so arranged that any number can be put down at different times and driven by the same motive power.

Messrs. Richard Hornsby and Sons, of the Spittlegate Iron Works, Grantham, had a very good portable engine and a combined thrashing, shaking, and finishing machine. But their chief strength was shown in their reapers, which were there in all their useful varieties. The "paragon" machines of this class differ from all others in having a really direct action for the knife. The cutter bar is directly jointed to the crank shaft, so that it will work freely at any angle. This firm have also introduced a grinding and sharpening machine, which supplies a want which has long been felt by users of reaping and mowing machines, in which so much depends upon the knives being kept properly sharp. The machine is a small bevelled sharpening roller which is actuated by a treadle, the operator sitting in front of the machine. The angle given to the sharpener is exactly adapted to the contour of the knives, and the work of sharpening is rapid and easy.

The Beverley Iron and Waggon Company, Beverley, Yorkshire, made their usual display of carts and waggons, for which they have been so long and so justly famed. Amongst this class of exhibits we particularly noticed their liquid manure or water cart, which is well-arranged and put together. This cart is fitted with the Beverley Company's patent iron wheels, and is admirably adapted for distributing liquid manure or water by means of a spread-board 6ft. long, which is suspended from the back of the cart and can be adjusted to the true level when working along the side of a hill. We also noticed a well-designed one-horse manual delivery reaper, which is fitted with Norfolk's patent self-acting tipping platform, and which has done some good work, and was a new exhibit with the Beverley Company. Whilst on the subject of reapers, we must not omit to notice this company's self-acting swathe-delivery reaper, which certainly embodies all the features that a true reaper should. This machine will pass complete through almost any gateway, commence cutting as it enters the field (being quite independent of scythemen), and deliver on either side, which enables it to work both up and down the same side of, or all round the crop, as circumstances may require. It is a noteworthy fact that the Royal Agricultural Society paid the Beverley Iron and Waggon Company twenty-five guineas for the use of one of these reapers in opening out the fields and dividing the lots of rye so as to enable the machines of other exhibitors to commence work without employing scythemen to clear the way for them, being a larger sum than was awarded to any other reaper in any class at Manchester. At this stand we also found a new turnip cutter, which struck us as being the handiest and most perfect out. Pickers are attached inside the front plate, and these clean the knives directly a cut is made. This ensures greater regularity in the size of the pieces cut, and a complete separation from dirt with less waste and labour. It thus has at all times empty knives to effect a clean and easy cut, it cuts the last piece irrespective of thickness, and it delivers the cut turnips direct into the scuttle perfectly clean, instead of taking them round in the barrel until forced out by the next pieces. The Beverley Company have also improved their linseed cake breaker by making the hopper for feeding variable, so that it can readily be fed with broken cake. Of course the company were as strong as usual in clod crushers and field rollers.

The special feature at the stand of Messrs. Amies and Barford, of the Queen-street Ironworks, Peterborough, was Campain's patent anchor, which is used in the roundabout or stationary system of steam cultivation. By the use of this anchor, which is self-moving and self-acting, the two anchormen as now employed are saved, the repeated digging up of the headlands is avoided, the annoyance and loss of time caused by the ordinary anchors drawing out is unknown, 40 per cent. of the daily expenses in wages is saved, and 10 per cent. more work can be accomplished. Indeed, the roundabout system can now be worked with the same number of hands as the direct system, while the items of coal and water carting are of course considerably less. Two anchors are employed occupying a position opposite to each othe on the headlands, and proceeding at righ angles with the plough or cultivator as it proceeds in its work. This firm also exhibited their combined straw, hay, and corn elevator, which is constructed both to carry straw from the steam thrashing machine, and hay, as well as sheaved or loose corn, during the hay and harvest seasons, with this additional advantage, that the machine is self-contained, and requires no separate horse works, and is consequently removed from stack to stack in much less time, while the machine is stronger and lifts to a great height. This is accomplished by Messrs. Amies and Barford's new plan of raising the body of the machine, by means of racks and pinions, to such a height that a horse can work underneath it, and the produce is then delivered to an elevation of 30ft., and the most severe part of the hitherto laborious manual operation is saved—a light nag horse being equal to the work. When harvest is over, the machine is let down to the ordinary height, and is then suitable for being driven in the usual manner from any steam thrashing machine. Another feature at this stand was Messrs. Amies' adjustable water ballast roller, which was described in the MECHANICS' MAGAZINE last year. In this roller, the cylinder is made of the best boiler plate, and is perfectly watertight, so that it can be loaded with water to any required extent. One of these useful implements has just been supplied by the makers to the town of Berwick-on-Tweed. It was 6ft. 6in. in diameter, 5ft. 6in. long, was made of 1in. plates, and weighed 12 tons.

Conspicuous, as usual, for steam cultivating machinery was the stand of Messrs. John Fowler and Co., of Leeds. They exhibited a new cultivator of strong and simple construction and 15ft. wide, in which the harrows are upon the principle adopted in this class of implement by this firm. They also exhibited a 14-horse power steam ploughing engine, and a single cylinder 10-horse power ploughing engine. The winding drum is worked by outside gear instead of inside as formerly, which enables the power to be obtained direct from the crank shaft. The pumps, cylinder, taps, &c., are all within the driver's reach, and in all respects these engines show careful design and sound workmanship. Messrs. Fowler have perfected five distinct systems of steam cultivation which are adapted to the various requirements of agriculturists.

Messrs. Kinsey, Norton, Hill, and Co., of the Robin Hood Works, Nottingham, are now making their combined vertical engines and boilers upon a principle which they were the first to introduce. This consists in fitting the engines to an independent frame or standard, which is attached to the boiler at the top by an expansion joint. The frame and base—which serves as a tank—are cast in one piece, and although apparently heavy the frame is very light, being cast hollow. The combined steam engine and steam pumper of this firm can be altered to either purpose in a few minutes by simply removing or replacing a cotter which connects the pump. Messrs. Kinsey and Co.'s horizontal engines present no new feature, except, perhaps, Mr. Kinsey's quick speed governor, with which all the engines turned out by this firm are now fitted. At this stand we were also shown some sections of a new wrought-iron tubular boiler, which is about to be introduced by Messrs. Kinsey. It is now in course of being perfected, and when completed we shall place full particulars before our readers. In the meantime, we may state that it appears well calculated for safety, economy, and rapid steam generation.

Messrs. Aveling and Porter, of Rochester, had two engines which well represented their special class of manufacture. There were a 12-horse winding engine for steam ploughing on the direct two-engine system, and an 8-horse agricultural locomotive engine.

The 12-horse engine was the embodiment of simplicity, carrying very little gearing, a great recommendation in any engine, especially those of this class. Messrs. Aveling and Porter's novelty, which is their road roller, was not admitted, on the ground that it was not purely agricultural. However, the Islington Vestry have arranged to hire, with a view to purchase, one of these excellent machines, so that it may, at any rate, be seen in the neighbourhood of the Show. For the sake of human nerves and horseflesh, we trust other vestries will follow the sensible example set by that of Islington.

The portable engines of Messrs. Allchin and Son, of the Globe Engine and Boiler Works, Northampton, are improved in various details since the last Show. They have steam jacketed cylinders; a precautionary measure now generally adopted by makers of these engines. The boilers of the engines made by this firm are made of Messrs. Shorbridge and Howell's mild steel, a metal which is specially adapted for this purpose. Messrs. Allchin's engines are fitted with every modern appliance, the working parts being accessible and well arranged.

Haymaking machines, horse rakes, chaff cutters, and other small implements were to be found in abundance at the stand of Messrs. Ashby, Jeffery, and Luke, of Stamford. This firm has brought out a new series of chaff cutters, which are alike notable for their excellence and their cheapness. Their No. E chaff cutter is specially worthy of a few words. It is a very strong machine, adapted for hand, horse, or steam power; it is mounted on a strong wrought-iron frame, strong wrought angle-iron legs; has three bearings to the main spindles; the cog wheels are all covered, and it is fitted on the near side with a safety lever for instantly stopping the feed rollers and for regulating the length of cut; width of mouth, 9⅝in. It can be easily worked by one man if required. It cuts ¼in. and ⅜in. chaff. Messrs. Ashby also had a very good high-pressure vertical engine and boiler, in which all superfluity is avoided.

The novelty at the stand of Messrs. Wallis and Stevens, of Basingstoke, is their new pattern elevator for ricking hay, straw, and other produce by horse power. This invention which effects a great saving in manual labour, has been tested during the season of 1869 in all localities and with all sorts of crops, with the most complete success. It has the great advantage that the chains cannot slip, however heavy the load. It will therefore take up a much larger quantity, and as it does not require to be driven at such a high speed it does not knock the crop about, as is the case with some of the quick-speed elevators. A small and light 1-horse gear has been designed specially for driving these elevators, which loads up on the frame of the elevator, and can be put down ready for work in a few minutes. The other exhibits of this firm consisted of a substantial 8-horse portable engine, thrashing and winnowing machines, ploughs, and harrows.

Messrs. Woods, Cocksedge, and Warner, of the Suffolk Iron Works, Stowmarket, have also a very well arranged vertical engine and boiler. The main shaft is arranged so that the fly-wheel may be placed on either side of the engine; thus two machines can be driven at once direct from the engine, one from each end of the crank shaft. The governor is on an entirely new principle; it is simple but very sensitive, and can be regulated so as to keep the engine at any speed desired. The feed pump is fitted with gun metal ball valves, and an extra valve is placed between the pump and the boiler, and close to the latter, so that the valves of the pump can be looked at or even removed without stopping the engine. The fireboxes are adapted for burning wood, coal, or coke. The crown of the firebox being kept low, there is always a great depth of water above it, which lessens the chances of the boiler being injured by shortness of water. The oil cake breakers exhibited by this firm are good; their No. 6 is a strong machine suitable for hand, horse, or steam power. It is fitted with double sets of rollers for drilling ordinary cake into fourteen distinct sizes. Messrs. Woods and Co. had a very good cart with a fixed sideboard and a movable frame, and which can be readily converted into a covered cart.

The "Clipper" 2-horse mowing machine has undergone one or two improvements since we last saw it at the stand of the Reading Ironworks Company. Our readers are familiar through our pages with the constructive details of this very successful machine. We need therefore only now point out that it combines strength and lightness in a pre-eminent degree. The recent improvements consist in the addition of a dividing shoe; a hollow wrought-iron connecting rod; a new and improved section of finger, the fingers being bolted instead of riveted; and an inner shoe of a flat instead of a sharp curve as has hitherto been used. The Reading Ironworks Company have attached a straw shaker to their horse thrashing machines, which meets a want that has often been felt and is now adequately provided for.

In the matter of carts and waggons we can refer with confidence to the stand of Messrs. William Crosskill and Sons, of Beverley. As far as the limited space allotted would permit, this firm made an excellent show of their speciality. Their 1-horse cart is fast superseding the old-fashioned 2-horse cart or heavy waggon. Their York pattern cart will be found admirably suited to light horses and ponies. The pair-horse waggon of this firm looks light, but a second glance serves to show that it is strong enough for any load that can be put in it for two horses. Their iron liquid manure or water cart is fitted with a simple valve arrangement, which can be opened and shut by the attendant as he walks by the side of the horse. This firm have brought out a new pig trough, which consists of a long iron trough with upright ends. By means of a moving shutter the pigs can be fed on either side of a wall. Messrs. Crosskill's clod-crushers continue to give every satisfaction, and the demand for them naturally increases every season.

We have now taken our readers through the body of the Agricultural Hall, which was appropriated to the exhibition of the heavy machines and the beasts, some of which were particularly heavy machines. Before leaving this part of the building, however, we may refer to the efficient arrangements which were made to guard against the spread of fire should an outbreak occur. There were three fire engines disposed at separate points of the building. Of these two were furnished by Messrs. Shand, Mason, and Co., of Blackfriars, and the third by Messrs. Merryweather and Sons, of Long Acre. These engines may also be considered in the light of exhibits by their respective manufacturers, and as such do them credit. Messrs. Shand sent a vertical single cylinder steam fire engine of the pattern supplied by them to the Metropolitan Fire Brigade. They also sent a manual brigade engine, which they have just completed for Beckenham. This suburb being beyond the limits of the metropolitan district, is required to have an engine of its own. Accordingly, a manual engine of the most recent pattern was ordered of and supplied by the above firm. The third engine was exhibited by Messrs. Merryweather, and was a steam fire engine, which they have just completed for the city of Trieste. It is one of their single cylinder class, and has a horizontal steam cylinder 6¼in. diameter, and a direct and double-acting pump 5¼in. diameter, with 18in. stroke of steam and water pistons. This engine is, we are informed, similar to the steam fire engine "Le Prince Imperial," one of the engines for which this firm gained the gold medal at the Paris Exhibition of 1867.

Proceeding again to the galleries, we will resume the notice we commenced last week by referring first to the stand of Messrs. Powis, James, and Co., of the Victoria Works, Vine-street, Lambeth. This firm exhibited their endless band saw machine, which is adapted for every variety of work. This machine is fitted with a swinging table, which can be adjusted to any angle, and has this great advantage over the circular saw, that it does not require one-tenth of the power to drive it. The new spring arrangement of this firm prevents the saws breaking, and gives the machine an important advantage. The upper saw wheel rides upon an adjusting spring, which allows it to yield freely to any sudden strain to which the saw may be subjected. In sawing sharp curves the saw is liable to expand, and in this case the spring acts mechanically in lifting up the slack without having to screw up a second time. In other machines it frequently happens, if the workman neglects to ease the saw, the instant the machine starts again the saw breaks.

Mr. John Davey, of Crofthole, near Devonport, sent one of his far-famed "excelsior" turnwrest ploughs, with swing furrow wheel. This implement is suitable for either level or hill-side land, and is admirably adapted for ploughing land for reaping or mowing by machinery, as it leaves no open furrows. By a simple contrivance all the moving parts are turned at once—one breast being placed in proper position, while the other is raised clear on the beam. This plough has done some very good work in the west of England. During the present year it has taken, in Cornwall alone, one prize—excelsior plough—two silver cups, eight champion prizes, twelve all-England, and numerous other prizes.

Messrs. Tangye, Brothers, and Holman, of Laurence Pountney-lane, London, had a variety of exhibits, their special steam pump, of course, forming a special feature. At this stand we noticed a very neatly designed and well-made horizontal expansive high-pressure engine, of simple arrangement and strong construction. The bed-plate, inner cylinder, cover, guides, and main journal are formed of one piece of metal, which, in form and proportions, is very perfect, and affords a strength and rigidity that cannot possibly be attained with the best fitted engines of the ordinary horizontal type. It is fitted with Tangye's high-speed regulating safety governor, which is of special description, and combines in the small space usually occupied by the ordinary steam stop valve, a governor, throttle valve, and stop valve complete. It is exceedingly simple and compact, and being driven at a high speed it is very sensitive, and the working of the engine rendered uniform under varying pressures of steam or sudden differences of load. A regulating arrangement is also combined for speeding the engine, that is, for determining the number of revolutions per minute at which the governor shall begin to operate. One important feature in this governor is its ability to shut off steam the instant the running off or breaking of the driving band takes place. In such a case the gravitating action of the governor balls immediately cuts off the steam, and prevents the engine over-running or causing any damage to the machinery driven by it. The throttle valve has one disc only, which is steam balanced, and by a peculiar arrangement of the steam ports the action of the engine is similarly controlled, both at the greatest rise and the greatest fall of the valve.

Mr. J. L. Norton, of 38, Belle Sauvage-yard, London, was well represented by his Abyssinian tube wells, which were there in various sizes. Mr. Norton also exhibited Mortlock's patent millstone dressing and levelling machine. This apparatus is exceedingly simple in construction and effectual in working. It dresses stones rapidly and

economically; one man can dress a stone in about an hour. It can be worked with one hand, no gearing or motive power of any kind being required.

Lever oil feeders and lubricators were well represented by two firms—by Messrs. B. Brown and Co., of 39, Charlotte-street, Blackfriars-road (who claim to be the original inventors of these feeders), and Messrs J. White and Co., of 15, Trinity-street, Borough. The former firm have an excellent oil feeder with a flat spring, and the latter firm have an equally excellent feeder with a spiral spring. Messrs. White also had a new lubricator—the "skylight" lubricator—which is an adaptation of Lieuvain's well-known needle principle to a small brass cup having a circular glass inserted in its top or cover; inside the cap is fixed a leather washer, making a joint which, when screwed down in its place, effectually excludes the air; the state of the oil in the lubricator will be always visible through the skylight in the top.

Not far from this stand we found a model of a house covered with Harding's flexible roofing, which is now so extensively used by the Admiralty, Metropolitan Board of Works, railway companies, &c. The price of this roofing has very recently been reduced to that of the common asphalte. At the late Amsterdam Exhibition a silver medal was awarded to Mr. Harding for this roofing, for its superiority and cheapness, although the price was then 50 per cent. above that of asphalte. Nothing more can be required on our part to recommend Harding's flexible roofing, seeing that it is patronised by the English and foreign governments. Before quitting the galleries we ought to notice the atmospheric churn, in which some improvements have recently been made. The Atmospheric Churn Company, whose offices are 119, New Bond-street, have effected a new arrangement for the admission of air. Formerly, it found its way in at the top of the tube, but now it is admitted by holes in the side of the tube, which is found to be a marked improvement. At this stand, too, we found Yeatman's yeast powder, which has only been before the public about six months. It is, however, a success, and from trials we have made of it we can speak to its efficiency and economy.

In the bazaar, which—as we stated last week—was devoted to a miscellaneous exhibition, we found several matters of interest to our readers. For instance, we there found Mr. Marsden, of 224, Kingsland-road, London, who had a good show of his metallic flexible tube joints in several varieties. This joint, which will be found described and illustrated at page 279 of our last volume, is a most important invention to sanitary engineers, as it prevents leakage when a settlement in the ground occurs. For ships this joint is invaluable for steam pipes, pumps, or other purposes, as it will give to the strain of the vessel without causing any leakage. For connecting locomotive steam engines to tenders it is an important improvement and advantage; in fact, this joint is for a number of purposes of great importance, for the ball and socket can be used as from the castings without grinding in.

In this part of the show we also found a very good rotary engine and pump, which was exhibited by the Rotary Engine Company, of 25, Old Jewry. This pump is the patented invention of Mr. Bennison, and was described and illustrated in the Mechanics' Magazine for July 23 last. Our high opinion of the valve of the pump at that time, which was based upon a careful investigation of its working, has by no means altered. Worked by hand at the Smithfield Club Show it came well up to the mark. The engine, as a motive power, is unequalled for economy, the small space it occupies, and from its capability of being reversed, stopped, and set in motion instantaneously from any point of the cylinder. It can also be used as a pump, and if it should choke, is immediately cleared by being reversed. A pump of 2½in. area, worked by hand, will discharge 20 to 25 gallons a minute, and by steam power 70 to 80 gallons. It also forms a most perfect air pump, blowing engine, or gas exhauster.

At another stand, not many yards from the last, we found the "Denmark" revolving pump, which was exhibited by Messrs. J. C. Wilson and Co., of 26, Martin's-lane, Cannon-street. This pump is constructed on the revolving principle. The method of forming the vacuum and of propelling the water, or lifting it, is the same as in ordinary pumps, viz., by means of a travelling piston. The difference, however, is that in this pump the motion is made continuous. This fact dispenses with the use of valves, which are only necessary to retain the water during the down stroke of a reciprocating motion. The advantages of this pump are those common to its class, and which are daily becoming better known and appreciated.

Mr. Jas. Smyth and Co., of 21, Little Trinity-lane, Cannon-street, had a display of their ingenious Panteles umbrella, which we noticed this time last year as one of the soundest practical improvements in these useful articles that has yet been adopted. The whole arrangement is thoroughly mechanical, and has stood the test of time so well that we cannot wonder at its success.

And thus we once more come to a close. We have taken our readers through what was this day last week a busy and crowded Show, and which has proved a great success. Now the great hall is deserted; the hum of the busy and inquiring throng is no longer heard, the bleating of sheep and the lowing of kine are silenced, the glories of the Smithfield Club Show of 1869 are matters of history. *Sic transit omnes gloria.*

THE FOOT BRIDGE AT PRAGUE.

OUR readers will doubtless remember that in June, last year, a new bridge was completed and opened at Prague. This bridge—the Franz Joseph—was designed and constructed by Mr. R. M. Ordish, of Westminster, upon his rigid suspension principle, which has been described in our columns. The success of this principle led to the construction of another bridge upon the same system and across the same river—the Moldan. This second bridge is for foot passengers only, and has the peculiarity of having one central tower and two abutment piers, thus forming two half spans. The special feature was necessary, in consequence of the character of the river bed and other local considerations. This bridge has a platform width of 11ft., and each span is 305ft. 6in. in the clear. The works of the bridge having been completed, it was tested on the 22nd and 23rd of last month by a commission appointed by the municipality, under the superintendence of the resident engineer, Mr. Max am Ende. The test load consisted of 42,500 bricks, equivalent to a load of 457,640lb., equal to a distributed load of about 64lb. per square foot. This load remained upon the platform for one hour. During that time observations were made at each span; the maximum deflection was 6¼in. and 6¾in. respectively; the anchorage chains extended over 1-12th and 1-8th of an inch. The estimated deflection was 7½in. On the 24th, the bridge was cleared of its load, when the permanent set was found to be half an inch, the anchorage chains having returned within 1-24th of an inch to their original position. The bridge is found to be exceedingly steady under uneven loading, and it has been exposed to heavy gales with like results. The success of these two bridges ought to lead to the carrying out of the long-talked-of bridge on the same principle over the Thames at Chelsea, and which is now represented by several dreary groups of piles.

NOTICES OF BOOKS.

THE name of Henry Booth has for many years past been known and honoured in the railway world. As one of the pioneers in the development of our railway system, he laboured diligently and indefatigably, first in connection with the Liverpool and Manchester Railway, and afterwards in the management of the London and North-Western system. Mr. Booth closed an active, useful, and eventful life on the 28th of March last, in the 81st year of his age. A brief notice of this sad event appeared in our columns at the time in common with our contemporaries. Since then a series of articles have appeared in the "Railway News," in which Mr. Booth's life and works were graphically portrayed. The information contained in these articles has served as the basis of a very interesting memoir,* by Mr. Robert Smiles. And we are very glad to find such a record of a man who for thirty-five years filled positions of the highest responsibility in the railway world. The volume before us is both interesting and instructive. It is interesting, inasmuch as it takes us back to the early days of railway development and carries us down the stream of time so that we note their progress as we go—matters which become dim and faded as memory adds year to year in its span. It is instructive as teaching lessons of patience and perseverance, and showing the never-failing results of the application of energy in a right direction. It also teaches us how a man apparently immersed in wearing and wearying pursuits can still find time for those of an elevating and more genial character. Mr. Smiles gives an insight into the early days of Mr. Booth, and touches upon the leading features of his life. His public career in connection with the railway interests is then placed before us, and, lastly, Mr. Booth's writings in the various positions he occupied in life are detailed and commented upon. Mr. Smiles modestly observes that he has only endeavoured to collect a number of facts and to string them together. That he has performed his task well and creditably is evidenced by the volume before us, whilst he has produced a memento which every railway man will desire as being that of their old and well-tried friend, Henry Booth.

Mr. Henry Dircks, C.E., has added another to the series of papers he has recently contributed on the subject of patent law. At the Social Science Congress, at Bristol, in September last, Mr. Dircks read a paper "on the policy of a patent law," which, with the discussion that followed, has been published in pamphlet form, by Messrs. Spon, 48, Charing Cross. This paper is a critical notice of the arguments employed by Mr. Macfie, M.P., in support of the abolition of patents, and with which our readers are familiar. Mr. Dirck's paper is a refutation of the absurd and untenable positions advanced by the honourable member for Leith. After Mr. Dircks' paper, we have the interesting discussion, which shows Mr. Macfie to have been wholly unsupported—a result scarcely to be wondered at. The only matter for wonder is how Mr. Macfie can find heart to reiterate statements and propound views which are exactly opposite to those entertained by every other member of society except Mr. Macfie himself.

"England at Home" is the name of another little brochure, published by Messrs. Cassell, Peter, and Galpin, of La Belle Sauvage-yard, London. It is written by Mr. W. E. Littlewood, M.A., and is a familiar description of the principal physical, social, commercial, and topographical features of England and Wales. These are important points of view from which to teach children the specialities

* "Memoir of the late Henry Booth, of the Liverpool and Manchester and afterwards of the London and North-Western Railway." By Robert Smiles. London: Wyman and Sons, 75, Great Queen-street, Lincoln's Inn-fields. 1869.

of their own countries. Here, youngsters are taught the geological character of England and Wales to begin with; they are then made acquainted with our rivers, our railways, our people, and our animals, in a plain and concise manner.

A few more annuals have reached us. The first of these is "Gutch's Literary and Scientific Register and Almanack" for 1870 (Stevens, 421, Strand). This is the twenty-ninth year of publication of this useful pocket companion, which contains as usual the pith and marrow of all branches of science. It is a compilation of special value to those whose dealings with science are general, for here the main facts of every branch are collected and presented in a condensed form. It bears evidence of great painstaking on the part of its editor, and the result is a collection of useful matter and reliable scientific data nowhere else to be found in so small and handy a compass.

The diaries of Messrs. Letts and Co., of New Cross, of which we have received several specimens for 1870, continue to constitute perfect marvels of cheapness and usefulness. Nothing but the extensive patronage these books have could enable these manufacturers to give the public such rare value for their money. Letts' broad shilling diary is especially useful; it gives an entire week in the opening of two pages, and is ruled with double cash columns. At the end are pages devoted to each month for special monthly entries, and one for the reception of "Addresses, quotations, and other matters of interest." The sixpenny diary gives a whole page to each week, and is the handiest and most complete book for the price we have ever seen. The medical diary is adapted especially to the ordinary requirements of the medical profession, and is well suited for the purpose intended. It gives an opening of two pages to each week, the left hand being divided into the days of the week, the right arranged for lists of patients. All these diaries are replete with general and special information conveniently arranged for ready reference. To complete the list we may mention the appointment diary, which forms a very handy pocket book. It provides an hourly arrangement for the punctual keeping of engagements from 9 a.m. to 6 p.m. for every working day, besides giving space for casual memoranda to each. All of these productions well sustain the reputation Messrs. Letts have acquired in this direction.

TELEGRAPHIC NOTES.

WE have more than once called attention to the circumstance that it was intended to lay a submarine telegraph in China, in order to complete the communications with the East already in progress by the Falmouth, Gibraltar, and Malta, the Anglo-Mediterranean, the British Indian Submarine, and British Indian Extension Telegraph Companies. Pursuant to this intention a prospectus has been issued of the China Submarine Telegraph Company, in connection with the foregoing companies. The capital proposed is £525,000, and the first operation will be to lay a cable of 1,640 miles from the Straits of Malacca to Hong Kong (with an intermediate station at the French settlement of Saigon, in Cochin China), which is to be manufactured by the Telegraph Construction and Maintenance Company for £508,000. This cable will be shipped hence in the coming year and be completely laid by June, 1871. Subsequently a section will be laid from Hong Kong to Shanghai. Lines ultimately to Japan are likewise contemplated. All the companies with which the present extension is to be connected have agreed to make an allowance on all through messages forwarded over their cables from and to China, and, looking at the present enormous trade of China, not only with Europe but with America, and the prospects of its rapid increase, no doubt is entertained as to the paying capacities of the route, under a judiciously regulated tariff. The Board of Direction comprises the respective chairmen of the Falmouth, British Indian, Anglo-Mediterranean, and British Indian Extension Companies, the late Director-General of Telegraphs of India, the late Commissioner of Imperial Chinese Customs, and other persons of Eastern experience.

Last Friday a special general meeting of the shareholders in the United Kingdom Electric Telegraph Company was held, at which it was resolved *nem. con.* that the sum of £5,000 should be awarded to the directors for division among themselves; that the sum of £1,000 be awarded to Mr. Andrews, the secretary and manager of the company, and that £2,000 be equitably divided among the other officers of the company. The chairman (Mr. Crow) announced that the board expected to receive £24,000, which would be available for division among the ordinary shareholders; £7 15s. per share would absorb £21,000 of that sum, and the balance would be available for certain necessary expenses connected with the closing of the business. The preference claims and shares would be fully paid off by the close of this month, and by the end of January next he was of opinion the Government would have finally absorbed the company.

The United States' war sloop "Yantick" has been appointed by the American Government to make the soundings for the West Indian submarine cables from Jamaica to Porto Rico, St. Thomas, and Barbadoes. The British Admiralty have also ordered a vessel to continue the soundings from Barbadoes to Trinidad and Demerara. The "Yantick" is being fitted with sounding gear at the Navy Yard, Brooklyn, and will sail on January 1, under the command of Captain Irwin, United States' Navy, by whom the soundings between Jamaica and Panama have been already made in the "Gettysburg." The cables of the West India and Panama Telegraph Company, to connect Cuba, Jamaica, and Porto Rico, have been completed at the Silvertown Works, and the whole of the line will be shipped by March 15. An additional subsidy of £800 per annum has been devoted by Antigua to establish a station in that island.

The conflicting rumours which were rife last week respecting the transfer of the telegraph companies have been succeeded by a general conviction that the Government will take over the telegraph system on January 31, and that the payment of the £5,715,048 compensation money to the companies will be made some time between January 28 and February 5.

The cable from Land's-end to Scilly has been overhauled for about a mile from the Land's-end, and a kink has been found and buoyed. If splicing apparatus can be obtained in the neighbourhood, the kink will be cut out and the cable spliced immediately, weather permitting, and then it is hoped that messages will be passed. It will be remembered that the weather was exceedingly rough and the sea high when the cable was laid.

The arrangements for the commencement of telegraphic business at the Norwich Post Office have now made good progress. There will be five instruments in operation; messages will be written on the ground floor, and will then vanish to the second floor by means of a hoist. The Crowland office has been fitted up with desks; it is not expected to be opened for some weeks, as the route to be taken by the wires has not yet been decided on. Telegraph wires have within the last few days been extended to the new office in Guildhall-street, Lincoln.

It is stated that a company has been incorporated, under the title of the International South Transatlantic Telegraph Company, and will be shortly introduced to the public, for the purpose of establishing telegraphic communication between Europe and the continent of South America, under the concessions obtained by Mr. P. A. Balestrini from the French, Italian, Portuguese, Danish, and Brazilian Governments, and that the cable has been already contracted for by the firm of Aubert, Gerard, and Co., of Paris, London, and Harburg.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

THE RELATION BETWEEN THE INTENSITY OF LIGHT AND THE CONSUMPTION OF GAS—EVAPORATING POWER OF PETROLEUM—TINNING IN THE WET WAY—NEW LIGHT FOR PHOTOGRAPHERS.

A VERY important observation in relation to the illuminating power of gas has been made by Professor Silliman, of New York. Hitherto it has always been supposed, and nothing would appear more reasonable, that the amount of light obtained from the combustion of gas is simply in proportion to the quantity of gas consumed. From a series of experiments, however, made by himself and others, Professor Silliman has arrived at the conclusion that the intensity of gas flames, that is the illuminating power, varies—at all events, within the ordinary limits of consumption—as the square of the volume of gas consumed. The truth of this theorem was proved in the following simple way. Two gas flames, one at each end of an ordinary 100in. photometer bar, were made to give the same amount of illumination, which was accomplished by placing the Bunsen's disc midway, and regulating the flames until the consumption and the illumination were equal. The disc was then moved on the bar to a point just four times as far from one flame as from the other, that is, the bar being 100in., the disc stood at 80, or 1 to 4. The distant flame was then increased until equality of illumination was again obtained, and the consumption in the two flames was noted. The nearer flame was found to consume 3·66ft., and the distant one 7·32ft., or exactly double. Now, if the old rule of correction had been followed, a double consumption of gas would have been calculated to produce only twice the amount of illumination; but the actual increase observed was as 4 to 1. The importance of this observation, when the illuminating power of an observed consumption is calculated to a standard consumption, becomes very great. As an example, Professor Silliman supposes a gas consumed at the rate of 3½ft. to give an observed effect of 20 candles. By calculating this to a standard consumption of 5ft. on the old rule, the result would be only 28·57 candles, but calculated on the theorem above stated, the result becomes 40 candles, or 40 per cent. higher. Supposing the theorem to be true, and sufficient truth of it is promised, the practical inferences are worthy of all attention. The observation shows that the maximum economical effect is obtained from the consumption of gas in burners of ample flow. When an equal diffusion of light over a large space is required, numerous small jets may be used with the most advantage, but when the maximum intensity from a given volume is desired, intensity burners of large consumption, Professor Silliman says, are plainly indicated. Considered in relation to the legal examination of gas these observations are of the utmost importance, and it is to be hoped that the matter will receive the serious attention of all interested in the matter.

When speaking of the use of petroleum in locomotives a short time ago we neglected to give our readers the comparative evaporating power of petroleum and other fuels. So far as "patent fuel" is concerned—and we rather think that of the Aberdare Company is used—the results were as follows:—Weight of water evaporated by 1 kilo. of oil, 10·9 kilos.; by 1 kilo. of patent fuel, 7·9 kilos.

In addition to the information which we gave some time ago relative to tinning in the wet way—a process which is claimed by others besides Dr. Hiller, from whom we quoted—we may give the following particulars. When articles tinned by the galvanic process are heated to the melting point of tin, they assume the appearance and acquire the solidity of articles tinned in the usual way. In some cases, however, the galvanic process is especially advantageous. Thus it becomes possible by means of it to tin copper gauze, and when gauze so tinned is heated great additional strength is given by the wires becoming soldered together by the melted tin. By raising the temperature sufficiently high to effect a slight fusion of the underlying metal a surface of alloy is obtained, tinned copper, for example, assuming the appearance and properties of bronze. In the same way copper coated with zinc by a similar process acquires, when heated, the appearance of brass. It is mentioned also that zinc coated with tin by the galvanic process is more malleable when heated than zinc alone and solders well; and it is supposed that the alloy formed may be capable of useful applications.

We may mention here that Dr. Monckhoven has come to London to exhibit a new artificial light especially applicable to photography. It is procured, we believe, by rendering cylinders composed of magnesia and titanic acid incandescent by the oxyhydrogen flame. Our photographic notes will soon give our readers full particulars of this light.

ANGLO-FRENCH COMMUNICATION.*

By Mr. Zerah Colburn.

(Concluded from page 421.)

While it is fairly open to doubt whether any of us will ever live to see a practicable railway tube laid across the Channel—open to doubt, too, whether such a tube is even required at all—there is still a sort of bewitching interest in speculating upon the mere possibility of such a thing; and it is thus that this meeting may be supposed to have resolved itself into a committee of inquiry upon this very point. Can the tube be made at all? Can it be made before those now unmarried shall have lived to see their grandchildren? If it can be done, and done off hand, so much the better, always provided that the tube is what is wanted. Here, as with Mr. Midshipman Easy, there is no help for it but to "argue the point." Assuming, then, for the sake of argument, that the particular tube now under consideration can be made, and safely laid, can it be done as its proposers estimate, within a period of three years and a half, or only within from six to ten times that space? The tube is to be made of something like half a million tons of cast iron, and to believe that it can be made at the rate of 100ft. forward a day, as estimated, is to believe that nearly 500 tons of castings, all ready, or rather, supposed to be ready, to go exactly together, each casting weighing about eight tons, can be loaded on horse trucks, or hand trucks, and carried through the tube itself for an average distance of ten miles, unloaded, placed in position, the thousand or more connecting bolts, for which the holes have been previously drilled, secured in their places, the joints made good with lead, and a great deal of other work carried on, all within a confined space within which, partly from the machinery to be employed, hardly more than a dozen men, if as many, will have room to work at all. The British Association was lately occupied with a most able and most interesting description of this plan, and the Society of Arts may therefore be inclined to examine this, the very important point which, at the recent meeting of the Association at Exeter, appears to have escaped all examination whatever. The "point" might be "argued" still further, but let argument be dropped now for individual consideration of the subject.

Another plan of making and laying the tube has been proposed—a plan based, like the others, upon a general estimation of what is possible and probable. It is to construct the tube, in long lengths, within a dry dock in shore, and to float out these lengths, successively joined together, until the opposite coast is reached. The tube would be floated, not, certainly, upon the surface, but by means of buoys, just clear of the bottom, the tube being again grounded as soon as it had been advanced a length.

Few propositions, perhaps, connected with engineering upon which the writer has ever reflected, have, at the first view, presented more apparent impracticabilities than this one. But the more he has examined it, the more have the means by which these difficulties may be overcome disclosed themselves. It was enough to know, from the first, that the plan was not in contravention of any law of nature, and therefore was not impossible. Like each of the other plans already noticed, its execution would necessarily be in the face of tremendous difficulties—difficulties which, perhaps, not one of the various projectors of Channel tubes have fully estimated, and which it, is beyond doubt, they have not, because they cannot have fully provided for. But the whole progress of engineering has shown that what were once seeming impossibilities have long since become useful and familiar facts. The difficulties supposed to be once overcome, it is plain that a plan whereby (say) a thousand feet or more of the tube could be put together in a single day, in the open air, as many men being employed upon it at once as could find room to work with advantage upon that length, would have a manifest superiority over any other in which each length of a few feet (say ten), must be wholly completed before another length could be begun and especially in which the whole work of making up the tube is to be carried on within the tube itself, the parts being brought to the front in trucks drawn by horses to a distance successively increasing to 20 miles.

In no way could the segments of a tube be so rapidly got into place and secured together as in a dry dock, the semicircular bottom of which, of cast iron, would conform exactly to the tube itself. The segments would be lowered into place, those for the lower half of the tube centering themselves, while those for the upper half would be temporarily supported upon centres so made as to be readily taken down when the key segment was got in and secured. The seaward end of the tube, of great strength, would, of course, be closed, and it would be provided with suitable fittings for attaching the powerful hauling-out tackle to be used when the successive lengths were floated. The dock gates would close around the tube so as to form a water-tight joint. The tube would be of such dimensions and thickness that, previous to putting in the brick lining, its own weight would be as nearly as possible exactly the same as that of the sea water displaced, so that, of itself, it would, so to speak, neither sink nor swim. Approximately, a 14ft. tube would displace about $4\frac{1}{2}$ tons of water for each foot of its length, and it would of itself weigh about $4\frac{1}{2}$ tons for each foot of its length when its thickness, allowing for all flanges and bolts, was 5in. or say $4\frac{1}{2}$in. between flanges, and this would be the proper thickness for strength, irrespective of any consideration of displacement. The weight of the tube would require to be very accurately adjusted, since a difference of thickness of 1in. would cause a difference of weight of 900 tons in a 1,000ft. length, hence a difference of but one-thousandth of 1in. would represent very nearly 1 ton in weight. Each length would require to be brought to the exact limit of flotation by means of adjustable weights. As the tube would require to be adapted to the irregularities of the bed of the Channel, each length of a thousand or more feet, would have a ball and socket joint, and it would be here, and here only, that the sinking weight would be applied, and the holdfasts for the lifting and sinking tackle attached. Probably 100 tons might be necessary to prevent any movement of the tube, especially in shore, from the force of the sea, for at a depth of a few fathoms the force of storms would not be felt at all. The tube being made in segments, the construction of ball and socket joints would be attended with no difficulty. They would require to be made of great strength, not merely to provide sinking weight, for they would receive the whole strain of the hauling-out tackle when the tube was advanced seaward. A thickness, for the ball and socket, of 8in., this thickness being continued a little more than 10ft. each way, would give 100 tons of sinking weight. The motion at these joints would be but slight, yet this slight amount of motion is none the less necessary to enable the tube to adapt itself to varying gradients. It is at least remarkable that any strictly rigid tube should ever have been proposed, as more than one has been, for a line having gradients varying from nearly level to 1 in 100.

When a length of tube had been completed and was ready for launching, its in-shore end would be closed watertight, the buoys made fast in place, the dock gates opened, and the sea admitted, upon which the tube would be drawn up well clear of the bottom by means of the adjustable tackle connected with the buoys, and the whole of the tube, of whatever number of connected lengths of 1,000ft., would be drawn out to sea for a distance corresponding to the length last added. It would then be lowered again upon the bottom, the in-shore end of the tube being left well within the dock gates, which would then be closed, and the water in the dock pumped out.

In buoying and advancing the tube, especially when extended nearly 20 miles, it contained nearly half a million tons of cast iron, the chief resistance, in starting, would be, occasioned by not its weight, for except at the ball joints it would have no preponderating weight in the water, nor by its skin friction, for this at a rate of motion of 1,000ft. only in an hour would be comparatively trifling—but the real resistance would be from inertia. It might be supposed that as much effect would be produced by the hauling-out tackle, if made fast to the rock of Gibraltar, as if to a great iron sea-serpent, 20 miles long, and weighing half a million tons. But let us see what this enormous resistance would be. Let the rate of onward motion of the tube be 3in. per second, a rate at which 1,000ft. would be gained in 400 seconds, or one hour, six minutes, and forty seconds; not so very long a time after all. To give this rate of motion would require the same force as would be necessary to lift the whole weight to a height of the 1-85th part of an inch, a distance almost too insignificant to deserve consideration until it is understood that 500,000 tons are to be lifted to that height. It is then that the 1-85th part of an inch begins to look respectable, the work done being equal to that in lifting 1 ton to a height of nearly 500ft. or, in other words, 500 foot-tons, which is about the energy contained in a 32lb. cannon ball when it leaves the gun fired with a full service charge. But these 500 foot-tons do not need to be exerted within one, two, or three minutes, and if a quarter of an hour be taken to get the sea serpent under weigh, the mean rate of progress during that time being $1\frac{1}{2}$in. only per second, the tube will have progressed $112\frac{1}{2}$ft. before it is in full swing, and thus the pull will average less than 4 tons during that time, after which all further resistance from inertia ceases. Now 4 tons is a little more than the breaking strength of the little Atlantic cable of 1858, and is well within the working strength of the steel wire ropes employed to haul Fowler's steam ploughs. Next comes the resistance of skin friction. The surface of the tube, supposing it to be 14ft. in diameter and 20 miles long, and having no outer flanges, would be nearly 107 acres, whereas a ship like the "Hercules" has but little more than three-quarters of an acre of immersed surface when ready for sea. But the "Hercules" has run nearly 15 knots an hour with a net thrust upon her screw shaft of about 50 tons, the resistance being nearly all skin friction only. Skin friction is believed to increase as the square of the velocity, so that the 1,000ft. an hour of the sea serpent are to be compared to the 90,000ft. an hour of the "Hercules," not in the proportion of 1 to 90, but in that of the square of 1 to the square of 90, or as 1 to 8,100. Thus the "Hercules," weighing 8,600 tons, requires 50 tons pressure at the stern to drive her at her full pace, while the serpent, with a skin nearly 150 times more expansive, and a weight nearly 60 times greater, would nevertheless, upon the law of the square, require a pull of less than one ton to tow it by the nose, if serpents have noses, all the way across the Channel, its inertia having been already overcome. And yet this mass of iron, if thrown into the form of a cube, would measure about 136ft. on a side.

That the tube would follow its nose in a straight line, and not in the zig-zag outline of a Vandyke border, known in America as the Virginia fence pattern, may be safely concluded, not only from a consideration of the reasons which would compel it of necessity to follow a straight course, but from the analogy afforded by Mr. Macsweeny's jointed steamboat, the "Connector," which plied a few years ago between Newcastle and London, and by Mr. John Bourne's trains of connected boats on the Indus. Although neither of these systems proved commercially successful, both demonstrated that a long train of boats connected together will follow as true a course upon water as will a long train of waggons on a railway.

The tube would be hauled forward, as each fresh length was added, by tackle worked from a vessel steered well ahead, on the true course, and there moored fore and aft, to prevent swinging out of her position, although the whole work of advancing the tube would or should be performed at slack high water. In such a great work, so important to the commercial interests of the whole world, it is not unreasonable to suppose that a convention would be entered into by all, or nearly all, commercial nations sanctioning the authority of a marine police to guard the hauling chain from dragging anchors.

But now come, perhaps, the principal questions of all. The maximum tidal current, at spring tides, in that part of the Channel where the various proposed tubes are intended to be laid, is, by Burwood's tables, 3·3 knots an hour, or 5·57ft. per second. This is, however, the surface velocity, in mid-channel. The velocity at the bottom, in the deeper portions, is probably *nil*. In a communication recently made public by Mr. Cromwell Varley, the eminent telegraph engineer and electrician, occurs the following interesting and even amusing passage:—

"It is well known to all nautical men that the action of the waves decreases very rapidly in descending. I believe I am correct in stating, in proof of this, that a diver, engaged upon the wreck of the 'Royal George,' accidentally left his spectacles on the wreck off Spithead. The depth of water was about 16 fathoms. A violent storm prevented him from resuming operations for about nine days, and, on again descending, he found his spectacles in the place where he left them.

"It is also well known to all nautical men that currents extend, as a rule, to only a small depth; and it is a common practice to moor a boat in deep water by tying a kettle or some heavy object to a line, and dropping it overboard into the comparatively still water. This mode of anchoring has

* Read before the Society of Arts.

been frequently used by the surveyors in the Atlantic.

"As a further proof of the complete stillness at the bottom, I may mention the cable that was laid from Varna to Balaclava. This plain gutta-percha covered wire was wholly uninjured by those terrific storms which destroyed so many English vessels."

With 100 tons of anchoring weight at the shore end, and with the same weight at distances of every 1,000ft., and with the immense inertia of a tube weighing 4,500 tons between each pair of sinking weights, there would appear to be but little danger from the action of storms—a conclusion borne out by the fact that iron sewer pipes are often extended well out to sea, as at Brighton, and remain there without disturbance. The waves come end on with the tube, and are harmlessly divided, whereas, did they strike it athwart, they would lift it upon the beach. Experiment, during a single winter, would determine whether even so much as 100 tons sinking weight would be required at each 1,000ft. It might turn out that 50 or even 25 tons would suffice, in which case the work of lifting and grounding the tube, as about to be described, would be very greatly lessened. The most critical point in the whole scheme is probably that of lifting and lowering the tube at each advance. Before going into this, it will be as well to see what is to be done at each sinking weight or ball joint in deep water, say 33 fathoms at high tide. There are 100 tons of dead weight to be lifted, besides the inertia of 1,000ft. of tube to be overcome, and there is also the weight of the lifting chain itself and its supporting buoy. Taking the weight and inertia to be overcome as 150 tons, and supposing the lifting chain never to be strained beyond 3 tons per square inch, the sectional area of the chain would be 50 square inches, so that each 15ft. of its length would weigh a ton. As the chain would commence two fathoms and a half from the bottom, we will allow that for slack, and its own weight would thus be between 13 and 14 tons. This it would be necessary to buoy with the utmost care, for, once lost, the chain could never be recovered in water of greater depth at most than 15 fathoms. The buoy, weighing probably 5 tons of itself, should have at least 20 tons of additional supporting power, and would thus require to be of a capacity of 875 cubic feet, corresponding to a cylinder 8ft. in diameter and 18ft. long. Were it not that the buoys must be kept out of the way when the lifting tackle is attached, they would be best secured by passing the chain through them in a central pipe with secure stoppers, top and bottom. As they would, in any case, continue to float, this might, after all, be the best way of attaching them, when the stoppers were taken off at each lifting and lowering.

In getting into deeper water the chains would require to be lengthened, in 10ft. lengths, at every few advances, and in shoaling they would also have to be shortened in proportion. The lifting and lowering would be performed from a vessel alongside, and the lifting itself be effected by steam, acting directly upon the lifting chain, that is to say, a strong steam cylinder 5ft. in diameter, and permitting of a stroke of piston of 20ft., would be supplied with steam from a small boiler worked at from 125lb. to 150lb. per square inch, giving a lifting force of from 150 to nearly 200 tons. It is only by a direct steam lift that the effects of pitching and scending in the lifting vessel, and the varying level of the sea as the tide ebbs or flows, can be provided against, and that the elasticity of strain necessary for the preservation of the chain, and thus of the tube itself, could be secured. There are many details which would require to be carefully worked out before such an undertaking could be safely begun, but, without entering at greater length upon them here, it may be said that the principles upon which safety at each step would be reasonably assured have been considered with some care, and that there are no difficulties in the way which appear really insurmountable. It is not to be forgotten that a lifting vessel would be required at each 1,000ft. length, making no less than 110 in a length of 21 miles. There would be no difficulty in chartering the number, and the cost of the requisite fittings would not, in comparison with the whole cost of the work, be excessive.

The practicability of this making and laying a tube could be approximately ascertained by making two 500ft. lengths of tube half size, or 7ft. diameter and 2¼in. thick, closing their ends, and sinking and lifting them by means of three tug boats in different parts of the Channel. These lengths would weigh, including sinking weights, about 925 tons. If the experiment succeeded perfectly, as it should, in calm weather and at slack high water, it might be continued in rough weather and under the influence of the tidal current. The exposure of one or both these lengths, for a single winter, lying end-on to the shore, would afford very valuable experience. It is always to be borne in mind that after the tube is once laid, the brickwork lining and permanent way which will then be added will more than double its weight.

The tube, when laid for its whole length, would be bolted together at the ball joints by means of inner flanges, the whole then lined with brickwork and an inner iron casing, a permanent way laid, and would then be worked upon the atmospheric system.

The cost of the whole may be roughly estimated as follows:—

	£
500,000 tons of castings fitted ready for placing at £6	3,000,000
Brickwork lining	250,000
Dry dock, fixed plant, &c.	500,000
Floating establishment	1,000,000
2,500 workmen for two years at £100 per annum	500,000
Interest, during construction	500,000
Engineering and contingencies	250,000
Total, exclusive of approaches	£6,000,000

The plan suggested can claim no other advantages than these—viz., its practicability being assumed, it could be carried out in two or three years, including all the time expended in preparatory works. Almost any number of workmen might be effectively employed at the same time, and that in the open air, in full daylight, and out of the way of danger in case of accident. The tube would furthermore possess a flexibility which would ensure its following the irregularities, both vertical and lateral, which, with a careful survey in advance of the work, would naturally be found even on the comparatively smooth bed of the Channel.

It forms no part of the objects of the present paper, however, to put forward claims in favour of submerged railways. It is admitted, on all sides, that they cannot be made at a less cost than from £300,000 to £500,000 per mile. It is by no means certain that, even for the saving of half an hour and an immunity from sea-sickness, the majority of passengers would prefer a submarine journey of three-quarters of an hour, with the knowledge that but a few inches of iron were interposed between them and a second deluge. The fact that almost countless fleets of shipping were crossing 50 or 60 yards overhead, that a single ship, foundering then and there, and making its fatal plunge upon the tube, might work even greater destruction than its own; the reflection that scoundrels in the pursuit of mischief, or villains in the service of the devil, could at any time, and with almost perfect impunity, dispose of the tube for ever—all this would be anything but reassuring to the timid, and it would have its due weight with the strong.

In respect of economy merely, the interest upon a cost of £6,000,000, supposing the work to be carried out for that sum, and the money raised upon the guarantee of the English and French Governments at 4 per cent., would be £665 per day, or £231 per mile per week. It is not, perhaps, necessary, however, to assume that the work is to be undertaken as an immediately paying speculation, since other considerations of importance are involved in the question.

It is not to be lost sight of, however remote the bearing of the question upon the present subject may appear to be, that a sudden demand, within a couple of years, for half a million tons of cast iron, not for export, and not for immediately productive employment at home, would most certainly inflate the iron trade, and, indirectly, affect nearly every branch of our industry. If the price of pig iron advanced, as it not unlikely might, to the extent of 20s. a ton, this means 25s. or 28s. on rails, 30s. to 35s. on bars, and from £2 to £3, or even £4 on the higher qualities and lighter sections of iron. The very home demand—whereby we would be literally throwing our iron, and with it our money, into the sea, to no immediate profit, would give to other nations an advantage of which they would not be slow to avail themselves. Half a million tons of pig iron, when converted into rails, bars, or plates, and allowing for loss in conversion, would suffice for 2,000 miles of double line railway, or it would construct 75 miles of heavy iron bridges, weighing a ton per foot, or it would serve the shipbuilder for 250 hulls, such as, when fitted, would register their 3,000 tons each. The sudden abstraction of such a quantity for a single work, having no immediate prospect of success, might be attended with consequences which the whole country would long have occasion to deplore.

It has been mainly the object of the present paper, however, to examine into the engineering merits of the various schemes proposed for crossing the Channel, and the writer cannot close without expressing the belief that the balance of certainty, economy, and, all things considered, the safety and even the comfort of the travelling public, remains with a large and suitably organised Channel ferry service.

MANUFACTURE OF WHITE LEAD.

WHITE lead is generally manufactured in England by placing the metal over earthenware pots containing an acid, piling them up in layers, and covering them over with spent tan. An improvement upon this somewhat slow process has been patented by Mr. Joseph Major, of Swallow-street, Middlesex, in conjunction with Mr. W. Wright and Mr. G. H. Jones. The invention consists in the manufacture of white lead in closed chambers, heated artificially, and without the employment of spent tan or earthenware pots. The necessary vapours and gases are fed into the chambers containing the compounds to be converted into white lead. The invention further relates to the use of the vapours and gases under pressure in a closed chamber, although the white lead can be produced by this invention without the gases and vapours being submitted to pressure, but more time is necessary.

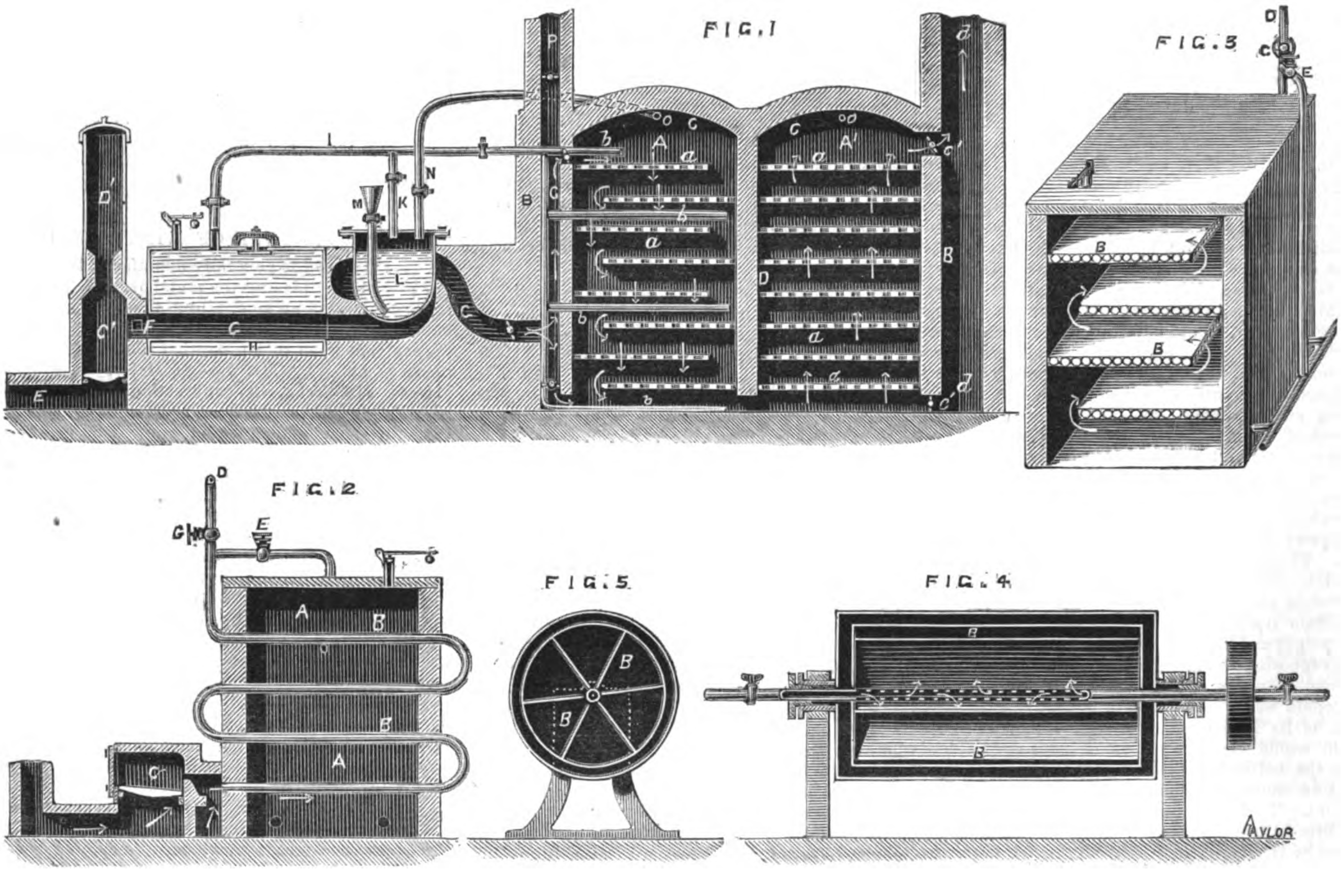
The apparatus employed in the manufacture embraces independent apparatus for feeding the vapours and gases and for regulating their supply, and for keeping the lead in continuous circulation through the closed chambers. This is accomplished by revolving surfaces inside a chamber actuated by machinery, upon which surface the lead is placed. The invention further consists in a method of treating the white lead, when produced, so as to decompose and remove any remaining acetic compound, and replace the necessity of washing the material. This is accomplished by currents of heated vapour or gases and air brought in contact with the material in the closed chambers, and circulating through them in contact with the materials, so as to deprive them of any superfluous compounds. They can, however, be washed and finished in the ordinary way. The article thus manufactured is completed by any of the well-known methods.

In our engraving fig. 1 represents chambers constructed for carrying out the first part of this invention. A A¹ represent the chambers; B B the wall; C C the roof; and D the separating wall. These chambers are shown with different arrangements of the shelves, for causing the gases to circulate perfectly and to permeate in a complete manner the lead under process of conversion into white lead. The chamber A has shelves *a a* made of any suitable material so disposed as to cause the vapours and gases to circulate in the direction shown by the arrows, as well as to permeate directly through from the top to the bottom, or *vice versa*. The second chamber A¹ shows an arrangement by which the circulation is effected longitudinally. Steam is supplied to these chambers both for heating and for furnishing moisture by the pipes *b b* shown in the chamber A. *c c* are the flues, so contrived as to cause the heated gases circulating through them to pass through several chambers or through one only or to the chimney *d*, without passing upwards through the chambers, the course of the currents of heated gases being regulated by the dampers shown in the flues *c c*. The lead is placed upon the shelves *a a*. The vapour of water and ammonia and acids and gases generated from carbonaceous materials for furnishing carbonic acid are fed into the chambers A A¹.

The mode of providing the necessary carbonic gases to the chambers is as follows:—C¹ is a charcoal or fuel burner and furnace, made so as to be self-feeding by the upper box D¹ D¹, and provided with a supply pipe E, by which the combustion may be sustained by pressure from a fan. F is an oxidising valve, which regulates the air admitted for effecting the combustion of the fuel. The products of this combustion pass under and through the boiler H by the internal flue G. The products after passing through the boiler pass under the vessels for generating the gases. One of these generators is shown at L. M is a pouring pipe; N is an exit pipe; K, a steam pipe adapted to the generator. By the generator gases can be made

APPARATUS FOR THE MANUFACTURE OF WHITE LEAD.

BY MESSRS. MAJOR, WRIGHT, AND JONES.



and sent to the chambers A A[1] by the pipe N. P represents an auxiliary exit or chimney used as a bye pass when necessary, as when the combustion is needed in the furnace C[1] and the products are not wanted to circulate through the chambers A A[1]; *d* is the working chimney, which receives the products from the chambers by either of the valves *c*[1] *c*[1] for sealing the chambers when required; I is the main steam pipe.

The mode of operating is as follows:—The lead, which is prepared so as to expose a large amount of surface, is placed on the shelves in the chambers; the chambers are then closed, and heated to a temperature of about 120deg. to 140deg. Fah. Steam is then directed into the chambers so as to convert a portion of the metal into hydrated oxide or oxide; this is continued for from ten to twenty hours. The chambers being raised to a temperature of about 120deg. to 140deg. Fah., the next step is to generate vapours in the generator L. These vapours are conducted by the pipe N to the upper part of the chambers at O. In these operations a sub-salt of lead is produced upon the lead in the chamber. The next step is to treat the lead with carbonic acid. This gas is prepared in the fuel burner C[1], and is fed into the chambers and caused to circulate regularly in contact with the materials so as to convert the sub-salts into carbonate of lead. During the conversion of the lead in these stages of the operation the temperature of the chamber is preserved at about 140deg. Fah., and the successive steps of the operation are repeated, care being exercised to regulate the supply of steam so as not to wash the lead nor to have it in too dry a state for treatment until the whole is converted into white lead.

Fig. 2 shows the arrangement of a pressure chamber A, fitted with valves E E for the purpose of regulating the pressure within. B B are pipes for circulating steam from a boiler, or hot air and gases from the fuel burner C, and forming also the shelves or supports for the lead. These pipes communicate with the chimney at D, which is provided with a stop valve G, so that the products of combustion, after passing through the pipes of he chamber and heating it, can be forced into the interior of the chamber and brought in contact with the lead, and thus after being employed as a means of heating the chamber when the same is heated by the gases from the fuel burner C, these gases are utilised in the decomposition of the sub-salts and in the formation of white lead; the heated gases, however, may be employed for heating purposes alone, and carbonic acid supplied to the chamber from some independent source in a heated condition or not. Fig. 3 shows the arrangement of the shelves in the chambers so as to cause circulation of the gases within it, the course of these currents being at right angles to those within the hollow shelves or pipes through which the heating current passes, and on which the lead or its compound is placed. The mode of operating is the same in the pressure chambers as that already described.

When circulating chambers are employed, in which the metal is kept in motion, the inventors have two cylinders, as shown in figs. 4 and 5; the inner one, which contains the lead, is made to rotate. It is a cylindrical vessel B with a number of radial shelves or gratings on which the lead is placed. These chambers are all fitted in a similar manner to those we have already described, and are fed with gases or vapours in a similar manner. The whole of the chambers have air-tight doors or openings for charging and discharging materials in manufacture.

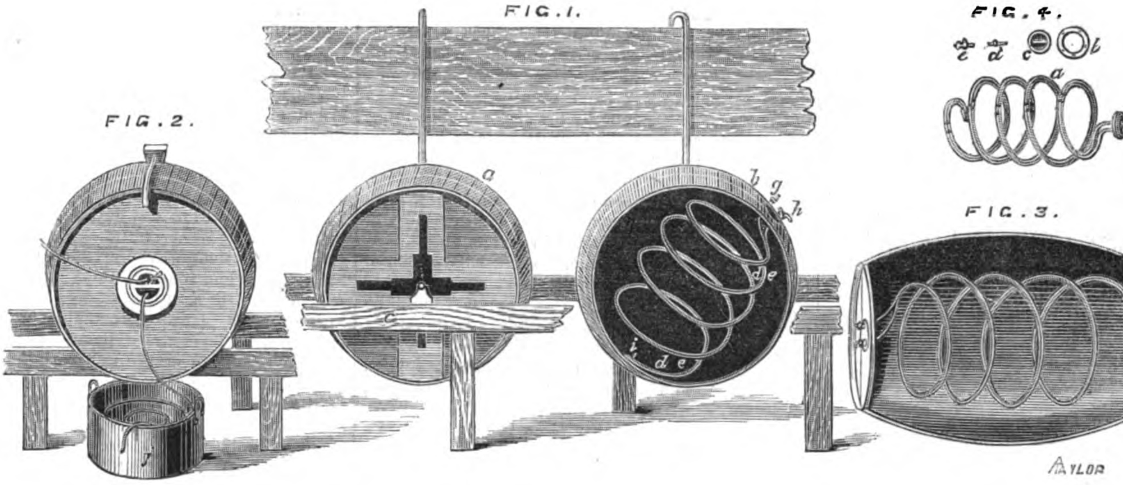
White lead so manufactured can be finished in the usual manner by washing, grinding, &c., but the inventors treat their products in a novel manner and on a new principle. They decompose any salts of lead remaining other than those proper to white lead, and this they accomplish as follows:—They pass into the chambers when containing the lead compounds produced in manufacture, ammoniacal compounds, and so decompose any remaining salts of lead other than those proper to white lead. After this treatment they raise the temperature of the chamber and its contents so as to remove the ammoniacal compound so formed, and thus avoid the necessity of washing. The lead is afterwards finished and prepared for general uses in the customary manner. White lead manufactured according to this invention is said to be free from all contamination, and is pure white lead. The process relieves the operation from its present dangerous tendencies, the workmen are never exposed to any dangerous or deadly fumes, nor is there any chance of loss of material in the process of manufacture. Time is also economised, the usual period required being about three months, whereas the inventors state that they can fully operate upon lead so as to convert it into white lead in from fourteen to twenty-eight days, according to the substance of the material operated upon, and in a pressure chamber they can produce it in even less time.

Professor E. V. Gardner, of Berners College, Oxford-street, has practically carried out this patent in all its bearings, and his exhaustive report is now before us. Upon all points the Professor obtained the most satisfactory results, as will be seen by the following extracts from his report:—"I do not hesitate to state, from my experience in these experiments, which I would observe are not laboratory experiments but practical operations (the chamber fully worked out being 4ft. by 2ft. 6in. by 2ft. 6in., and containing 3cwt. of lead), that white lead could be made by Major's process in twenty-eight days—*i.e.*, if the process were well conducted day and night unceasingly, and no time lost in raising the heat of the chambers day by day, as has been unavoidably the case in these experiments. I am also of opinion that the conduct of this process on an extensive scale, say of 500 or 1,000 tons, would show even more favourable results, and afford means of large and economical reductions in the cost of manufacture." Concerning the finishing process, the Professor writes:—"According to the plan at present pursued in making and finishing white lead, the material from the converting vessels being washed and ground, the cost is about £7 per ton. By this process (according to Major's patent) the converted material is treated with vapour of ammonia, so that any remaining acetate is decomposed; the salts of ammonia thus formed are then removed by currents of heated air, or by superheated steam. This newly improved finishing process, it is to be observed, is completed without removing the converted material from the chambers in which it has been treated."

OWNERS of runs in Australia continue to expend large sums of money in order to prevent the increase of the wild rabbits, which in some districts appear to have become a formidable nuisance. Mr. Robertson's run at Colac, for instance, says the "Melbourne Argus," is enclosed with stone walling, and a man with a pack of dogs is engaged in keeping the rabbits outside the boundary, while the run has been already cleared by the work of the rabbiters, at an expenditure up to the present date of £9,000. Dr. Stodart has four miles of walling completed, and has expended £1,300 in endeavouring to get rid of the bunnies. Mr. A. Murray has also expended some thousands of pounds in a like manner.

ATTEMPERATOR FOR UNION CASKS.

BY MR. J. A. BINDLEY.



ATTEMPERATOR FOR UNION CASKS.

THE defective construction of the tubes usually employed in breweries for attemperating by means of water has been carefully considered by Mr. J. A. Bindley, of Burton-on-Trent. He has, therefore, patented, through Messrs. Robertson, Brooman, and Co., patent agents, of 166, Fleet-street, the invention we are about to describe, and which is illustrated in the accompanying engraving. Mr. Bindley's improvement consists in employing, instead of the ordinary attemperator or pipe and casing, a pair of tubes laid side by side and coiled together into a large tapered spiral, roughly approximating in form to that of the cask in which they are to be employed, but of smaller diameter than the interior of the cask. One of these pipes is connected with the inlet nozzle and the other with the outlet nozzle usually employed with the ordinary attemperators, and the extremities of the pipes themselves are connected at the termination of the spiral, so that the course of the water is along one and back by the other throughout the entire spiral. This duplex spiral pipe being fixed by its inlet and outlet nozzles to the ordinary screw bung or closure of the cask, the spiral form given to the pipes enables them to be introduced through the ordinary aperture of the cask till the screw closure comes up to its flange and is secured. Mr. Bindley thus accomplishes the introduction into the cask of an attemperator of much greater surface area than that which is ordinarily in use, and, what is much more important, capable of uniformly regulating the temperature throughout the cask.

In the case of those attemperators which are fixed horizontally in the cask, projections or props are either attached to points on the spiral or are free to move thereon, or a ledge is made at the end of the cask for the point of the spiral to rest upon in employing any of these expedients, for the purpose of supporting the spiral when its axis is in a horizontal position. In the accompanying engraving we have represented the manner in which Mr. Bindley carries his invention into effect. Fig. 1 is a view showing two casks *a b* lodged upon a frame *c*. One of these casks is represented with the head removed, to show the coils of pipes *d e* forming the attemperator arranged in a spiral manner in the inside. The coils of pipes *d e* have been introduced into the cask through the bung hole, which is fitted with a screw collar for receiving a plate *f* on the end of the pipes, which plate has connected to it two taps *g h*, one to act as a nozzle and lead the water into the coil *d*, while the other tap *h* acts as the outlet to admit of the water which has returned through the coil *e* leaving the cask after having thrown off its cooling properties and reduced the temperature of the beer. The ends of the coils are connected so that a free passage for the water is established between one coil and the other. To prevent the ends of the coils being injured by coming into contact with the inside of the cask while they are being turned on inserting them, a projection is made on the ends of the same to act as a guide. Fig. 2 is an end view of a cask showing the face of the plate *f* and the arrangement of the inlet and outlet nozzles or taps *g h* fitted in the head or end of the cask instead of in the bunghole as in fig. 1. After the coils are screwed in, flexible tubes are attached to the nozzles, one of the tubes being in connection with the water supply, and the other in connection with the waste pipe or drain. The tub *j* is placed under the head of the cask for receiving the yeast thrown off. In fig. 3, we have shown a double coil of pipes fitted in a cask in a similar manner to that represented in fig. 2, and in fig. 4 we have illustrated the coils detached.

This apparatus has been at work for some time at the brewery of Messrs. Worthington and Co., where it gives every satisfaction; in fact, we are informed that its working has exceeded the inventor's anticipations. There is no projection or space left inside the cask which can harbour any sediment. The boss is constructed large enough to admit of a man's arm, so that the cask can at any time (when not in work) be brushed out without taking the head out. This attemperator has so many advantages which the practical brewer will at once recognise that it cannot fail to prove a success.

OPERATING TILT HAMMERS.

MR. T. T. PROSSER, of Chicago, has invented the method of communicating power to tilt hammers shown in the accompanying cut. His invention also relates to the arrangement for hanging, operating, and controlling the hammer, and the changing of the hammer dies both in the hammer head and in the anvil. The invention has recently been patented in England. Our engraving shows a vertical longitudinal section of the apparatus.

A A are two sills which form the base of the machine frame; B B are two posts inserted in the sills to receive the balance of the timbers composing the frame. Bolted on each side of the posts B are two longitudinal pieces C forming the side timbers. The rear post is longer than the front one so as to receive the cap or cross piece D on its upper end. By thus arranging the frame all parts are in position to receive the working parts of the machine and form a durable and perfect arrangement. On the upper end of the front post is the anvil block F containing the die E, which is made adjustable and is easily removed. Upon the upper and lower side of each end of the cross piece D are fulcrum or pivot boxes G to receive the pivots H passing through the vibrating arms I and I[1], which are connected together and held in position by the springs J and bolts K. The arms I I[1] are in pairs, and the lower pair of arms is shorter than the upper pair; and the arms are in each pair much further apart at the rear end than at the other or front end; the rear ends of each pair are not connected, whilst the front ends are. The lower pair of arms is connected at the front end by a pin *l* and the bolts *m*. In the middle of the pin *l* is a box *n*, to which are attached the eccentric rods that vibrate the arms I[1] and I by means of the eccentric O on the shaft P, which is connected to the short arm of the levers *q*, which are pivoted at R, and, as the eccentric is driven by the friction wheels S, it will be evident that as the foot is placed on the footboard T the shaft P will vibrate and bring the wheels in contact with those driven by the belt *u*. As the pressure of the foot causes an increase of friction the vibrations correspond therewith. As the hammer is moved up and down by these vibrations the faster the vibrations are the harder the hammer will strike, and the slower they are the lighter blow the hammer will strike. As these motions are under the control of the operator by means of the footboard T and lever *q* the machine can be made to strike just such a blow as the operator may desire.

The upper pair of arms is longer than the lower arms, and their front ends are permanently attached together by means of two plates *w*, through which the hammer shank passes, and to which it is attached by the nut V on the upper end of the hammer shank. The hammer shank near the hammer W is square, and the hole in the plate on the under side of the arms through which it passes is made to correspond therewith, whilst the hole in the upper plate is round. The object of making the hole and hammer shank square is to keep the hammer from turning. By connecting the lower arms to the upper by means of the springs the inertia of the hammer when at rest and the recoil when at work are overcome in such a manner as to relieve the machine from those violent shocks incidental to the common tilt hammer and to convert them into useful effect, for as the hammer is thrown up by its momentum to a greater distance than the movement of the eccentric an increased amount of tension is imparted to the forward springs, and when the hammer descends the increased tension causes it to descend with an increased velocity and additional force, thus being enabled to strike a much quicker and harder blow than can be done by the machines now in use. As the springs admit of a ready adjustment by means of the bolts and nuts it can be readily adjusted to a rapid or slow motion as desired, and as the shock consequent upon a vibrating motion caused by a reverse movement is all taken up by the springs its motions are all easy and it cannot fail to be durable, the importance of which advantages must be evident to all who are acquainted with the vast amount of labour performed by this class of machines.

THE public will be glad to hear that "Seely's Pigs," which gave occasion to so long and fierce a controversy, have at last been sold to Mr. Dixon, of Laurence Pountney-hill.

DR. LIVINGSTONE.

SOME further intelligence of Dr. Livingstone has been received, in the form of a very interesting letter from the veteran explorer himself. The letter, which we append, was received at Zanzibar on the 2nd of October last, by Dr. Kirk, who, in forwarding it to the secretary to the government at Bombay, wrote as follows :—

"Zanzibar, October 2, 1869.

"Sir,—I have the honour to enclose herewith, for the information of the Right Hon. the Governor in Council, the copy of a letter from Dr. Livingstone, dated the 30th May, 1869, and received at Zanzibar this day. The requests made by Dr. Livingstone in a previous communication that reached on the 7th ult., having been already complied with, I shall lose no time in supplying the things herein demanded. There will, however, be some difficulty in getting faithful men, as the Arabs of Unyanyembe, being of the El Hoathi tribe, are by no means loyal subjects of Seyd Majid, and, as Dr. Livingstone tells us, still engaged in the slave trade.—I have, &c.

"JOHN KIRK."

The following is Dr. Livingstone's letter :—

"Ujiji, May 30, 1869.

"My dear Dr. Kirk,—This note goes by Musa Kamaals, who was employed by Koarji to drive the buffaloes hither; but, by overdriving them unmercifully in the sun, and tying them up to save trouble in herding, they all died before he got to Unyanyembe. He witnessed the plundering of my goods and got a share of them, and I have given him beads and cloth sufficient to buy provisions for himself on the way back to Zanzibar. He has done nothing here. He neither went near the goods here nor tried to prevent their being stolen in any way. I suppose that pay for four months in coming, other four of rest, and four in going back would be ample, but I leave this to your decision. I could not employ him to carry my mail back, nor can I say anything to him, for he at once goes to the Ujijians and gives his own version of all he hears. He is untruthful and ill-conditioned, and would hand off the mail to any one who wished to destroy it. The people here are like the Kilwa traders—haters of the English. Those Zanzibar men whom I met between this and Nyassa were gentlemen and traded with honour. Here, as in the haunts of the Kilwa hordes, slaving is a series of forays, and they dread exposure by my letters. No one will take charge of them. I have got Thani bin Suellim to take a mail privately for transmission to Unyanyembe. It contains a cheque on Ritche, Steuart, and Co., of Bombay, for Rs. 2,000 and some forty letters, written during my slow recovery. I fear it may never reach you. A party was sent to the coast two months ago. One man volunteered to take a letter secretly, but his master warned them all not to do so, because I might write something he did not like. He went out with the party and gave orders to the head man to destroy any letter he might detect on the way. Thus, though I am good friends outwardly with them all, I can get no assistance in procuring carriers, and as you will see if the mail comes to hand I sent to Zanzibar for fifteen good boatmen to act as carriers if required, 80 pieces of moritrano, 40 pieces of kinitra, 12 farasales of the beds called jamsain, shoes, &c., and I have written to Seyd Majid begging two of his guards to see to the safety of the goods here into Thani bin Suellim's hands or into those of Mohammed bin Sahib.

"As to the work to be done by me it is only to connect the sources which I have discovered from 500 to 700 miles south of Speke and Baker's with their Nile. The volume of water which flows north from lat. 120 S. is so large, I suspect that I have been working at the sources of the Cango as well as those of the Nile. I have to go down the eastern line of drainage to Baker's turning point. Tanganyika, Nyige Chowambe (Baker's ?) are one water, and the head of it is 300 miles south of this. The western and central lines of drainage converge into an unvisited lake west or south-west of this. The outflow of this, whether to Congo or Nile, I have to ascertain. The people of this, called Manyema, are cannibals, if Arabs speak truly. I may have to go there first, and down Tanganyika, if I come out uneaten, and find my new squad from Zanzibar. I earnestly hope that you will do what you can to help me with the goods and men; £400 to be sent by Mr. Young must surely have come to you through Fleming and Co.—I am, &c.

"DAVID LIVINGSTONE.

"A long box paid for to Nijiji was left at Unyanyembe and so with other boxes."

At the last meeting of the Royal Geographical Society, Sir Roderick Murchison made the following observations upon the above letter. He observed,—Much as I regret to find by this letter that the intrepid traveller had recently to contend with difficulties owing to the conduct of certain Arabs, it is for us to admire still more the indomitable resolution with which he was preparing to conclude his labours. The very words preceding his last paragraphs express so entirely what I surmised would be my absent friend's final endeavour, that I cannot forbear from quoting them :—"As to the work to be done by me (says Livingstone) it is only to connect the sources which I have discovered from 500 to 700 miles south of Speke's and Baker's with their Nile." Let us, therefore, hope that this intended effort has before now been crowned with success, and that no long period will elapse before we are rejoiced in welcoming him at home. At the same time, we must be prepared for the possible but not probable contingency that the waters of the Lake Tanganyika should be found not to flow northwards into the Lake Albert Nyanza, but to be deflected to the west. In that case, if Livingstone should be adequately supplied with carriers and provisions, he will, I doubt not, follow these waters, and thus being led on, perhaps, to the Congo, we may once more be subjected to a long and anxious period of suspense.

ROYAL POLYTECHNIC INSTITUTION.

THE annual distribution of certificates and prizes to the successful candidates of the evening classes connected with the above institution took place last Friday, in the large theatre of the institution. Dr. Brewer, M.P., occupied the chair, and was supported by the Rev. J. B. Owen, chairman of the Polytechnic, the Rev. Prebendary Mackenzie, M.A., hon. manager of the educational department, Professor Pepper, and Mr. T. W. Tobin, the secretary. In opening the business, the Chairman referred to the great success which attended the candidates sent by the institution to the various examinations; it was a circumstance of which they might well be proud, that the late Prince Consort's prize had been carried off a second time by a member of the Polytechnic Institution, the fortunate winner this year being Mr. W. J. Wilson, who was very successful in various branches of study and had received a large number of prizes. The Rev. Mr. Mackenzie said that her Majesty the Queen, on learning that the Polytechnic had carried off the Prince Consort's prize for two successive years, had graciously forwarded for the use of the library a copy of her works with an autograph inscription. Dr. Brewer then handed the prizes to those winners who were present to receive them, and the proceedings closed by a hearty vote of thanks to the chairman, moved by the Rev. J. B. Owen, seconded by Professor Pepper.

ROGERS' LIFE-SAVING APPARATUS.

OUR readers will be glad to learn that the development of Mr. Rogers' apparatus for saving life at sea is progressing satisfactorily, as, indeed, such a valuable and practical invention deserves to progress. An interesting series of preliminary experiments with this apparatus were made under the superintendence of the inventor and the officers of H.M. gunnery ship "Excellent," at Whaley Island, last week, with the most useful size, viz., a 3½-inch mortar. The practice showed the accuracy of aim with which the projectile could be thrown, and the distance was very great for the quantity of powder used. A projectile weighing 12lb., with double line, the weight of which was 10lb., was thrown a distance of 198 yards with the incredibly small quantity of 1¼oz. of powder. The whole of the experiments were carried out to the entire satisfaction of all who witnessed them. We have before fully described and commented upon this meritorious invention, which has so impressed the Government with its utility that Mr. Rogers has been instructed to have the full size appliance made in her Majesty's Dockyard at Portsmouth, under his personal superintendence. We trust the inventor will reap that reward he so richly deserves for the time and thought he has devoted to this means of rendering aid to our seamen and ships in distress.

WE understand that it has been decided to make no re-appointment to the office of Master of the Mint. The present Deputy-master, Mr. Freemantle, will preside over the establishment, which will be attached to the Treasury.

HYDRAULIC MACHINERY FOR WAREHOUSING GRAIN.*

By MR. PERCY G. B. WESTMACOTT.

THE subject of the paper of which the following is an abstract was a description of the hydraulic machinery for warehousing grain at the Liverpool Docks. Blocks of warehouses have been erected by the Mersey Dock and Harbour Board, ably designed and executed under the supervision of Mr. Lyster, the dock engineer, for the stowing and conditioning of grain and bread stuffs. The dock upon which they are situated is 570ft. wide by 230ft. broad at one end and 180ft. at the other, with a depth at high water spring tides of 34ft. over the sill of the gate. The blocks on the east and west sides of the dock are 650ft. long, and that on the north end 185ft., the whole range being 70ft. wide. The buildings contain five stories. Above the fifth or upper storage floor, and partly in the roof, is placed the machinery floor, and below the quay level are wells and arched subways for the reception of the underground machinery. The total storage capacity of the floors, exclusive of the quay floor (at 4qrs. to the square yard) amounts to 196,000qrs. of grain. The ends of the east and west blocks are constructed to receive iron chambers for conditioning grain on the Deveraux system in order to prepare it for the market by drying. The steam engine, the prime mover of the whole plant of machinery, was of 370-horse power, and that, in addition to driving the machinery in the warehouse, supplied power working for the lock machinery and the bridge over the entrance, consisting of two 60ft. and one 50ft. bridges, twelve sluices, ten powerful ship capstans, and twenty-four machines for opening and closing the lock gates. From returns taken of the importation into Liverpool of the different descriptions of breadstuffs for the years 1858—63, it was estimated that the warehouses should be constructed capable of working 250,000 tons per annum, irrespective of other ordinary merchandise.

Having described the principal processes required to be performed by the machinery, and the best means likely to secure the requisite power, and especially the kind of power, and the most convenient, practical, and least costly method of applying and distributing that power, the writer stated that it was found after experiment that no system of motive power or combination of systems could be found to meet those requirements in the aggregate with so much effect, convenience, and economy as the hydraulic system. Having noticed the facility with which this power had been conveyed for long distances at the Birkenhead docks, and also the advantages or otherwise of propelling grain horizontally by means of screws, the author stated the results of the latter system. At sixty revolutions per minute (the maximum effective speed) grain could be discharged by a screw in use at a certain brewery at the rate of 6¾ tons per hour, being at the rate of 1-25th-horse power for every foot run. With a screw subsequently put into operation of 12in. diameter, and driven at the rate of seventy revolutions per minute (the most effective speed), thirty-four tons of grain per hour were discharged. The effect upon the grain in the latter case was marked, it being rubbed and polished, and thereby improved in marketable condition. But the long distance through which the grain had to be conveyed horizontally, amounting collectively to 7,000ft., and the power required to perform the operation, even with the best form of screw, rendered it expedient to seek some other method less absorbent of power, and recourse was had to endless travelling bands.

Experiments were made with a 12in. band, constructed of canvas and india-rubber. It was found that a speed of 9ft. per second could be attained with heavy grain, and still more with peas. The amount of grain discharged by the 12in. band at the speed of 8ft. per second, was at the rate of about thirty-five tons per hour. Further trials were carried on with an 18in. band, made of two plies of stout canvas, covered with vulcanised india-rubber. To meet the requirements of passing grain from off the straight bands to either side at certain points along the travel, several contrivances with air blast, and brushes driven from the band itself, were tried, but with indifferent success. Both methods were objectionable on account of raising dust, and the friction of the brush proved in time injurious to the band. The idea then occurred of diverting the line of the current of grain by means of an upward deflection of the band, thus casting the grain clear from the band

* Institution of Mechanical Engineers.

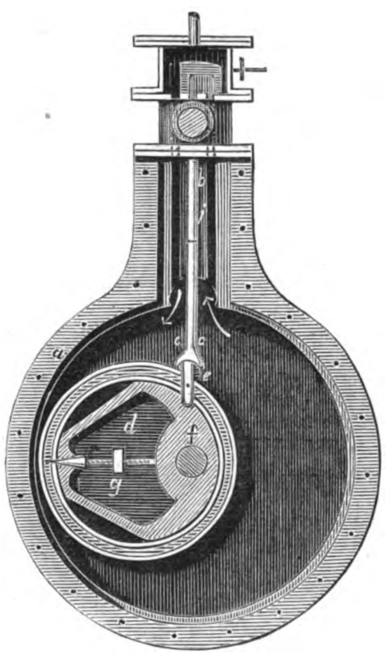
into the air for a short distance; it could then be received upon a band travelling in any other direction, and, if necessary, could be passed round the warehouse from one side to the other, or even make a circuit of three sides of the block, according to the method in which it was intended to dispose of it, or the place in which it was to be deposited. There were fifty-six spouts, 8½in. square, from the upper to the various other floors. No difficulty was experienced in keeping the grain on the band, but it was found necessary to glide the grain on to it from the feeding hopper through a spout rather less than half the breadth of the band, at an inclination of 42½ deg., which would impart a velocity to it on falling approximating to that of the band. The maximum amount of heavy grain conveyed by the 18in. band was at the rate of seventy tons per hour; the power required for driving the band when fully loaded was ascertained to be equal to about 1-70th-horse power effective per foot run.

The paper then described the boiler and engine, &c., and also other apparatus with which the warehouses are furnished, including the cranes and the two accumulators, each of which latter is weighted with a load of seventy tons, acting on a ram 17in. diameter, and the auxiliary accumulator with a load of 100 tons, acting on a 20in. ram. The form of tub in which grain is lifted from the holds of ships, and the hoppers through which it is passed for various purposes, having been minutely described, the author detailed the construction and capacity of the elevator, which consists of a wrought-iron bucket, capable of containing about 21 cwt. of grain. It was slung in an arrangement of bars and levers, provided with guiding rollers, which enabled the bucket to run in special grooves to the top, for the discharge of the grain into the upper hopper, which communicates with the same cross bands that convey the grain from the hopper under the crane. Casks, bags, and other merchandise might be raised or lowered by two classes of machines—one by means of the hydraulic cradle hoists, of which there were twelve; the other by means of twenty jiggers. Twelve double-acting 10 cwt. jiggers had also been added to the plant in the central block, to lift and lower goods to and from railway waggons. The paper lastly directed attention to one of the great advantages which the hydraulic system possessed in so eminent a degree, namely, the facility afforded for the extension of power to any point where the demand for additional contrivances to save time and hand labour was felt.

ROTARY ENGINE.

MESSRS. JOHNSON and GILL, of Unstone, Derby, have lately patented some improvements in rotary engines and pumps. In their invention a direct rotary motion is given to the shaft of the engine, the moving parts working perfectly steam-tight with a small amount of friction. When motion is given from an external source to the shaft, the piston will act as a pump for raising or forcing water. The engine consists of a cylinder, secured on a foundation, and having a central shaft working in bearings at each end. On this shaft is mounted a circular piston, revolving eccentrically around and within the cylinder, at the top of which the inlet and exhaust pipes are applied. Between the ports a slot is cut, in which a slide has a reciprocating motion, and which, therefore, separates the exhaust from the feed, the slide also working in grooves cut within each end of the cylinder, and being attached to the piston by a saddle and knuckle joint in connection with a belt surrounding the piston but not rotating with it. By this arrangement the eccentric motion of the piston causes the slide to ascend and descend at each revolution of the shaft, always maintaining a perfect steam stop. The piston is made in two parts, so as to ensure its being steam-tight. The interior contains a spring adjusted to any pressure by a screw to bind or thrust its periphery against the surface of the cylinder, and the outer ring is divided into two parts, so that it can be sprung to the face of the side. The end also of the outer ring contains a groove, wherein the ring attached to the strap works, which connects the slide to the revolving piston. The strap works through the end of the slide, and is connected also to a spring at the top of the slide to keep it to its work. When used as a pump the chest and feed valve is not required; the feed and exhaust ports serve equally for the inlet and discharge of the water, the engine working in exactly the same manner as when steam is applied.

We show a vertical section of the engine, in which *a* is the end plate or cover of the engine, with the groove *b* cut in it for the reception of the sliding top *c*, attached to the cylindrical piston *d* by means of the jointed strap *e* and loose ring in the centre of the piston; *f* is the shaft to which the piston is fixed, and *g* is the screw rod which forces the piston against the interior of the cylinder; *h* is the feed pipe, and *i* the exhaust port, the arrows showing the direction of the steam or water and the consequent course of the piston. The slide

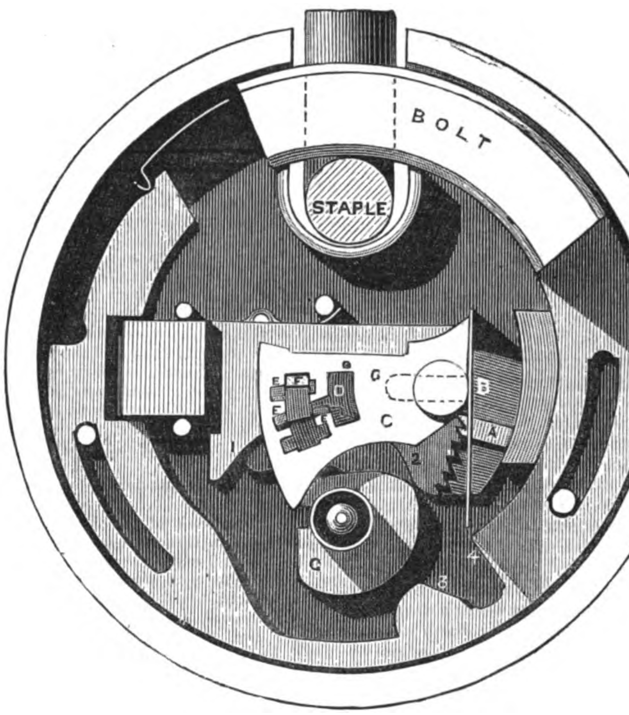


rises and falls within the groove and within the slot *j* in the upper part of the engine above the main cylinder, being always attached to the ring enclosing the cylindrical piston, so as to acquire a reciprocating vertical motion caused by the eccentric movement of the piston. The engine will be found applicable to driving screw propellers where direct rotary motion is desirable, as it occupies a very small space in comparison with that necessary for a reciprocating engine.

A FIR tree, 139ft. high, and 71in. in diameter, has recently been felled in the woods belonging to the family of Zichy, at Arwa, in Hungary. It has been taken to Hamburgh to be formed into a mast.

THE "CITADEL" WEDGED BOLT ORBICULAR PADLOCK.

BY MR. HODGSON.



THE "CITADEL" ORBICULAR PADLOCK.

IN our number for July 23 last will be found an illustrated description of Mr. Hodgson's patent wedged bolt lock, which marks a material advance in the locksmith's art, and puts as material a check upon fraud and violence. We now illustrate herewith the same principle applied to a padlock, which we have just examined. This padlock, from its perfectly round shape, combines security with elegance and convenience, and altogether with the entirely new internal action, affords the greatest security possible in a padlock. It has no ears or shackle, the orbicular bolt turned by the key forming the shackle, and being secured internally by a single and simple action of the bolt of a complete "citadel" lock. Referring to our engraving the action of the padlock in opening is as follows:—The key, on being inserted and turned, first elevates the levers or tumblers C to their proper height for the stamp F on the secondary bolt to pass forward into the true gatings E. It then shoots the bolt sufficiently far forward to disengage the teeth of the wedge A from those of the bolt. This additional outward movement of the bolt is effected by the action of the key upon the outer incline in the secondary bolt before it has entered sufficiently far into the talon D of the bolt to move it backwards. The key, continuing its rotation, then elevates the wedge lever A sufficiently to bring the block or wedge A opposite to the slot B in the bolt, and then withdraws the secondary bolt in the usual way; and when it meets the talon of the orbicular bolt rotates it until it arrives at the keyhole.

In locking this padlock, the key on its entrance first acts on the talon of the orbicular bolt 3, 4, and shoots it sufficiently far round as may be convenient; and then, by reason of the eccentricity of the drill pin, *i.e.*, the pin on which the key rotates, it arranges the levers and shoots the secondary bolt 1 into the orbicular one, and that in the usual manner. But so soon as the rear end of the slot B in the bolt has cleared the block or wedge A the latter is forced downwards by its spring bringing the wedge A opposite the solid portion of the rear end of the bolt and effectually preventing it from being forced back. In order that the inclined teeth on the rear end of the bolt may become engaged or interlocked with those in the wedge or block A, it is necessary that the bolt should be moved back slightly before the key is withdrawn. This backward motion is accomplished by means of a projection on the curtain G revolving with the key, the projection coming in contact with the inner incline on the bolt before the key arrives at the position for enabling it to be withdrawn from the lock. In our engraving the projection or collar

on the curtain G has just left the incline and completed the action of locking. The bolt and wedge are thus interlocked together, and no lifting of the wedge can be effected until the bolt has been disengaged from it or moved outwards slightly, as previously described. We thus see that the exposure of the shackle and the weak points of the ears and rivets—inherent defects in the ordinary padlock—are here perfectly remedied. These special advantages, together with the very perfect mechanism of the interior, enable us to recommend it as a safe and reliable fastening. We should add that the manufacturer of and agent for the orbicular padlock is Mr. James Hodges, 114, Chancery-lane, London, who has favoured us with these particulars.

A NEW DIGGING MACHINE.

We recently witnessed the working of a new rotary digging machine, which is on view to those interested in such matters in the Ashburnham Grounds, Chelsea. This machine is the invention of M. Florent J. Vandenvinne, who has successfully shown what can be done in grubbing up land. The apparatus is worked by steam, and is self-contained and self-propelling. It consists of a boiler and engine, which works a couple of vertical shafts in front of the machine, and which are armed with a series of horizontal picks. As the earth is brought down by the picks it is mechanically filled into a set of buckets on an endless band. These buckets deliver the soil into a revolving platform carried over the machine, and which delivers it out behind over a shoot. The propulsion is obtained by means of an endless platform working over pulleys, and which forms a way for the machine to travel on, and which it lays as it proceeds. This machine is exceedingly ingenious, and can be regulated to work in a direct line or in an upward or downward direction. We shall place an illustrated description of the apparatus before our readers next week.

STREET TRAMWAYS.

A vigorous commencement has been made this week with the first of the tramways authorised last session for the metropolitan district. The London Street Tramway Company have commenced the construction of their double line from Whitechapel to Bow, and the men, of whom a larger number will be employed next week, are making rapid progress. The rails are 4in. broad, and have a groove on the face for the flange of the wheel. They are spiked upon longitudinal sleepers of Baltic timber, 6in. by 4in. The sleepers are bedded in cast-iron chains, and kept in gauge by cross ties of iron, dovetailed at the ends into the chains, and abutting upon the sides of the sleepers. The roadway is of the best description, having a considerable depth of concrete under the paving stones. The sleepers will be packed with Portland cement, which will furnish a firm and durable bearing. The contractors for the line, which is about 2¾ miles in length, are Messrs. Fisher and Parrish, who, so far as can be judged at present, seem determined to make a thoroughly sound and durable road whereon the great experiment of street tramways is to be first tried in the metropolis.

THE AMERICAN NAVY.

It is stated that the Secretary of the Navy, in his forthcoming report, will recommend a total reorganisation of the United States navy, the sale of all the old and worthless vessels of the "Isherwood" class, and the construction of some new and more serviceable ships. The force of the navy now amounts to about 200 vessels. The Secretary will suggest that the peace footing be fixed at about 180 vessels. He is also in favour of subsidising lines of ocean steamers, and alludes to the advantages which the country would have derived in the late war from the possession of a steam flotilla, such as the British Government has at its disposal in the event of hostilities. The tonnage of England, France, and the United States is contrasted, with, as may be judged, results by no means favourable to the United States. On the subject of docks and navy yards the Secretary has some recommendations to make. He considers the Brooklyn yard too small, and will advise that ground be purchased on the North River for a more commodious establishment. The foreign squadrons, he thinks, should be increased and strengthened. All this can be accomplished on the same amount of money as was appropriated last year.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular December 16.)

Since our last circular of the 9th, the transactions reported in the chemical trade may be considered a fair average; a slight lull in the alkali trade was experienced in the early part of last week, but towards the close some considerable shipping orders were given out. For home consumption there has not been such a perceptible falling off in orders as is usual at this time of the year; consequently, prices are very firm, with every prospect of an appreciable increase at the turn of the year. In minerals, no sales of importance; the deliveries have been chiefly on account of contracts. Since the advance in iron, a proportionate increase in the value of the ores has not been realised, many of the ironmasters having contracted for five years' supply, based on the late low prices of iron. In metals, the Scotch pig iron market has been very excited during the week, and prices are now higher than they have been for a considerable time. The market closes with prices still tending upwards. Copper is in quiet demand; the standard advanced 10s. per ton at the last sale of Cornish ores. Tin is fluctuating in value, but stocks of English are low. Lead in moderate demand, and selling freely at our quotations. Spelter quiet, and prices unaltered. Soda: Soda ash for contracts is still being placed at the old rates of £7 on 48; and of caustic at £13 on 60. The demand for soda crystals has somewhat abated, prices remaining at £3 17s. 6d. Salt cake, not pressing, and firm, at 57s.; bicarbonate, dull, at £9 5s. Nitrate of soda has fallen again, though it is still, at £15, considerably above its value. Potash: muriate very firm, and in inadequate supply, prices tending upwards, from £7 7s. 6d. to £7 12s. Saltpetre: a somewhat more active market, prices ruling from 22s. to 23s. 6d. foreign; and 26s. 6d. English refined. Alum: though heavily contracted forward, is sold at the old rates of £6 5s. for loose lump; and £7 for export in barrels; and £7 for ground. Ammonia: sulphate in tolerable request, at £15 10s. for 20, to £17 for fine white; muriate sells at £22 to £23. Copperas: green and rusty, at £2 10s., in ordinary demand; dry, very active, at 50s. Pyrites: the market is now somewhat more regularly supplied, prices ruling as before. Lime: in phosphate there is less doing, at 52s. 6d. for 65; bleaching powder firm, at £8 for 35, with considerable quantities still to place; disinfectants, at £5 5s. per ton for best kinds, selling freely. Manganese: in slow requirement, at 90s. for 70. Iron ores: hematite sells at 15s. to 18s.; oolitic is finding new consumers, at 6s. to 8s., in Staffordshire. Guano: best Peruvian obtains still £13 7s. 6d. to £13 10s.; seconds in slower demand.

Metals.—Iron: Scotch pigs steady at 56s. 11d. to 57s. Cleveland, very firm, at 47s. for forge, to 51s. 6d. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire bars, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: quiet; English tough, £71 to £73; Chili slab, £67 to £68. Tin: fluctuating; English ingots, £118 to £120; Straits, nominally from £112 to £114. Lead: steady; P. G. best English soft pig lead, £19. Spelter: inactive. English, £20 10s.; Silesian, special brands, £19 10s. to £19 15s.; hard spelter, for export, £16 10s.

Obituary.

We have to record the death of Mr. George Smith, C.E., Belfast harbour engineer, which occurred on the 3rd inst. The deceased gentleman was in his 77th year, and had been for twenty-four years the resident engineer of the Belfast harbour. During that period Mr. Smith carried out a very large amount of work. Under his superintendence the new cut at the Queen's Island and the channel between the Twin Islands were formed, the contractor being the late Mr. Dargan. The Queen's Quay, Clarendon Dock, and all the timber wharfs on the Down and Antrim sides of the river were also constructed under his superintendence. The filling up of the old docks—Limekiln Dock running into Waring-street, Ritchie's Dock up to Great George-street, and Town Dock up High-street to where the Albert Memorial now stands, and all the extensive improvements in connection therewith, were executed by him. He was the architect of the new Harbour Office, and designed the lighthouse on Holywood Bank. Under his superintendence the Patent slip was constructed; he carried out all the reclamation improvements on the County Down side of the river; and the extensive ranges of sheds along the quays were all planned and executed by Mr. Smith. Indeed, all the great improvements in the harbour of Belfast completed during the past thirty years were carried out under his management.

Legal Intelligence.

VICE-CHANCELLORS' COURT.

December 15.

(Before Vice-Chancellor Sir W. M. James.)

ELMSLIE v. BOURSIER.

This was a suit for the purpose of restraining an infringement of a patent for improvements in machinery or apparatus for the manufacture of sheet tin by the importation from France of tin-foil manufactured according to the patented process.

The patent in question was taken out in March, 1859, by Mr. J. H. Johnson, as a communication from abroad by Jean Baptiste Ferdinand Masson, of Paris. In May, 1851, the letters patent were assigned by Johnson (by the direction of Masson) and Masson to the plaintiffs, upon the distinct understanding, as alleged in the bill, that the plaintiffs should have the exclusive right of selling in England tin-foil according to the invention, and should be free from the competition of any persons manufacturing tin-foil in any foreign country according to the invention, under any patent or *brevet d'invention* then or thereafter to be granted to Masson. In 1865 the defendant Boursier purchased from Masson his manufactory and business, and all his patents or *brevets d'invention* for France, with notice, as alleged in the bill, of the understanding between the plaintiffs and Masson. This agreement, which was in the French language, contained, among other provisions, the following:—"A l'egard de tous autres pays, l'Angleterre exceptee, pour laquelle M. Masson a deja pris un brevet, qui a ete vendu par lui, et dont il est bien entendu qu'il conserve le prix integral, M. Boursier pourra prendre a son profit, s'il le juge a propos, et si la legislation de ce pays le permet, les brevets d'invention et d'importation." The defendant Boursier had imported into this country from Paris tin-foil, which was manufactured according to the process patented in England, and now vested in plaintiffs by assignment. The question argued was whether the importation and sale of articles manufactured abroad according to the patented process was an infringement of the patent, it being contended on behalf of the defendant that there had been no infringement, as the subject protected by the letters patent was the particular improvements in the machinery for rolling tin, and not the metal itself or any new combination of metal.

Mr. Grove, Q.C., and Mr. W. N. Lawson appeared for the plaintiffs, and were stopped; Mr. Willcock, Q.C., and Mr. Locock Webb appeared on behalf of the defendant.

The Vice-Chancellor was of opinion that there had been a clear violation on the part of the defendant of the rights and exclusive privileges granted by the Crown to the patentee, and now vested in the plaintiffs. It was conceded that no one could use the plaintiff's process in England, and if it could not be done in this country it would be a very strange thing if a man, after parting with his rights over the patent in England, were to be allowed to sell the process in France, and enable it to be brought over here, so as to destroy all benefit of the grant of the letters patent. Being, therefore, of opinion that this obtaining from abroad and selling manufactured in this country tin-foil according to the plaintiffs' process was an infringement of the patent, the plaintiffs were entitled to an injunction according to the prayer of their bill.

Correspondence.

RAISING THE TEMPERATURE OF SOLUTIONS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Allow me to correct a rather important error in the resumé of my paper "on raising a higher temperature in certain solutions by steam of 212deg. Fah.," in your number of December 3. The mistake lies in the part of the following sentence which I have put in italics:—"The discovery was of immense practical value to Mr. Spence, and will be to every manufacturer who has *to boil down large quantities of saline solutions*, or to digest materials with high boiling points for a long time, since it shows that a naked fire may be entirely dispensed with." I feel more the necessity of explanation, as a large firm of salt manufacturers have to-day applied to me for details as to its applicability to evaporating brine. Now no boiling down can in fact take place at all, as the excess of temperature is afforded by the condensation of part of the steam, the water uniting with the salt, and the latent heat being developed into heat of temperature. You are perfectly correct as to its applicability to all cases of digesting saline or acid solutions where a continued high temperature is required

Hoping you will find room for this in your valuable journal,—I am, Sir, yours, &c.,

PETER SPENCE.

Pendleton Alum Works, Manchester,
December 14.

[We are much obliged to Mr. Spence for this correction. It would appear at first sight improbable that the steam condensed could compensate for the evaporation at the elevated temperature, but such is no doubt the case; and on reflection the reason appears clear.—ED. M.M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—S. C.—J. C. B.—C. R.—R. W.—E. T.—W. G.—L. and P. S.—J. W. T.—H. and M.—S. G. E.—T. W. T.—W. H.—E. B. J.—F. G.—A. H.—T. P.—J. W. P.—J. D.—P.O.—S. K. M.—J. E. L.—R. B.—J. M.—E. F.—J. R.—P. Meetings for the Week.

MON.—Society of Engineers.—Adjourned discussion on "Apparatus for Measuring the Velocity of Ships," by Mr. Vaughan Pendred, at 7.30 p.m.

TUES.—Institution of Civil Engineers.—Annual General Meeting, at 8 p.m.

Naval, Military, and Gunnery Items.

AN iron vessel called the "Haddock," loaded with guano, sunk in Galway Bay some three months since, was on Saturday last raised and brought into dock by Captain John Brennan, of City Quay, Dublin, a professional diver.

IT is said that a Russian line of steamers from the Black Sea to Bombay, *via* the Suez Canal, is about to be established, with contracts already made by one house at Moscow to ship 4,000 bales of cotton per week.

AT the usual monthly meeting of Clyde Trustees, held in Glasgow on Tuesday, the Lord Provost presiding, it was intimated that the revenue for November last amounted to £14,310 11s. 8d., as compared with £12,537 1s. 6d. for the corresponding period of last year, showing an increase last month of £1,773 10s. 2d. The increase for the past five months was £7,710 8s. 2d.

WE understand that about thirty of the new bronze guns were last week cast at Woolwich Arsenal. The analysis of the Indian bronze guns was only completed at the beginning of the week, when it was found that the composition consisted of from 8 to 10 per cent. of tin, the remainder being copper. The quantity of tin varied on account of its volatility and the difference in the length of time the alloy was being fused.

THE Inman steamer "City of Brussels," Captain Kennedy, has recently arrived in the Mersey, after a splendid run from New York. She discharged her pilot at 9.30 p.m. on the 4th inst., and anchored in the Mersey at 4.45 a.m. on the 13th. Allowing for difference in time and detention at Queenstown, the passage occupied the unprecedentedly short period of 7 days 23 hours 25 minutes. On the 9th with a south-west wind, she steamed 371 nautical miles, and on the following day she logged 365 miles.

IT will be remembered that in the fearful hurricane at St. Thomas on October 29, 1867, two of the Royal Mail Company's steamships were totally wrecked. The "Rhone" was lost on Peter Island, with 108 of her officers and crew, and the "Wye" on Buck Island, with 41 of her officers and crew, making a total of 149 lifes sacrificed in the two vessels. A very handsome memorial to Captain Frederick Woolley and the others who lost their lives on that occasion has just been completed in the Southampton Cemetery, and was recently unveiled and presented to the town by Alderman J. R. Stebbing, who was Mayor of the borough during the municipal year which immediately followed the hurricane.

A FURTHER reduction in the number of workmen employed in the shot and shell foundry and factory of the Laboratory Department in the Royal Arsenal at Woolwich, has been made this week by the discharge of 50 more skilled workmen. These continued discharges from this branch of the department are causing great surprise, as it is well known that there is a very inadequate store of common and shrapnel shells for the many hundreds of wrought-iron and converted cast-iron 64-pounder rifled muzzle-loading guns, and a still greater paucity of Palliser common and shrapnel shells, and Palliser shot for the large number of 7, 8, 9, 10, and 12-inch muzzle-loading rifled guns which have been manufactured.

A COMMENCEMENT has been made in Chatham Dockyard in building the "Rupert," iron-clad ram, 3 guns, 3,159 tons, 700-horse power. While fitted to act as a ram, this ship will carry a turret, and her armour will be heavier than any which has been used on any vessel. She will be supplied with the newly-invented double-balance rudder. She will be constructed in No. 2 dock; but as that dock is at present occupied by the "Sultan," in order to hasten the work the keel of the "Rupert" is being laid down, as a temporary measure, under No. 4 slip, and when the "Sultan" is completed the keel will be taken to pieces and removed to No. 2 dock, and the work of building the new ship will then be pushed forward. No. 2 dock will not long be occupied by the "Sultan," for the Admiralty have issued strict orders that she is to be so far completed as to be fit for floating out at the end of February or the commencement of March next.

Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending December 11, was 2,076. Total number since the opening of the Museum, free daily (May 12, 1858), 1,686,741.

FROM a statement of the business done by the New York Post Office with Europe for the month of October last, it appears that the total number of letters received and forwarded were 786,491, and the postage collected on the same amounted to 97,750 dollars 99 cents.

IT is announced that a great industrial and artistic exhibition is to be held at Turin in the year 1872, on the occasion of the completion of the tunnelling of Mont Cenis, but it is not stated whether it will be international, or confined to Italian productions only.

A COMPANY has been formed under the title of the East African Cotton Company, the object of which is the acquirement of land and cultivation of cotton in Zanzibar. The climate is stated to be specially suited for the cultivation of the superior qualities of cotton. The soil is rich, and labour is said to be plentiful.

IT has been definitively arranged that the eighteenth anniversary dinner of the members and friends of the London Association of Foremen Engineers shall take place in the City of London on Saturday, February 20 next, and that the arrangements and appointments in connection with it shall be similar to those which have proved so eminently satisfactory on former occasions.

IT is calculated that in the six months ended on the 25th of March last, copper, tin, lead, and other minerals were raised in Cornwall and Devon of the value of £637,028, and in the six months ended the 29th of September, £715,292. In the corresponding periods of 1868, the values were £553,652 and £581,200. The increase shown in the half-year ended September last is in the returns of tin and lead, the production of copper showing a serious decline.

YESTERDAY week there was an explosion of gunpowder at the Roslin powder-mills, Scotland, belonging to Messrs. Merricks and Co. The explosion occurred in a drying-room, which contained about 18cwt. of loose powder. The building was blown to pieces, and the roofs of several of the adjacent houses connected with the mills were much damaged. The report of the explosion was heard a distance of several miles. One man was slightly injured.

THE number of visitors to the South Kensington Museum during the week ending December 11, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,748; Meyrick and other galleries, 1,132; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,843; Meyrick and other galleries, 68; total, 12,791. Average of corresponding week in former years, 8,427. Total from opening of Museum, 8,993,807.

A CORRESPONDENT of the "Inverness Courier" writes:—Kildonan gold is all the rage this year, but we have good reason to believe that Abernethy gold will be in equal request next year. That some trace of the precious metal has been found very recently within the limits of this parish is beyond a doubt. The exact locality is not as yet given out by the discoverer, but we have every confidence in the party who made this discovery as one capable of judging of the possibility of gold being found.

THE fine collection of the late M. Lacaze has just become the property of the French nation, and now another well-known collector, M. Duclos, is about to present to the famous gallery one hundred of the best pictures in his collection. Already the whole of the new rooms of the Louvre are occupied, and great changes have to be made to afford space for the Lacaze Gallery; but the completion of the great gallery, and the removal of the Salle des Etats will soon furnish more space, which, however, will soon be filled.

THE following is a return of the quantity of coal exported from Grimsby during November, 1869:—To Belgium, 717 tons; Denmark, 342; Egypt, 918; France, 6,006; Hanseatic towns, 1,290; Holland, 547; India—British possessions, 686; Danish West India Islands, 186; Mecklenburg, 511; Norway, 1,594; Italy, 1,793; Prussia, 877; Spain, 761; Sweden, 2,259; Russia, 124; Turkey, 442; total, 19,053; coastwise, 3,179; total, 22,232 tons. Corresponding period, 1868, 20,049; coastwise, 3,502; total, 23,551. Decrease, 1,319 tons.

YESTERDAY week, at Stonehaven, on the Caledonian Railway, the boiler of a pilot engine attached to a goods train burst. The engine was blown to fragments, volumes of scalding water were thrown in every direction to a considerable distance; a large part of the line on which the engine had stood was blown away, and a hole of considerable depth made. One of the driving wheels was carried to a green about 50 yards from Stonehaven, while the sand box was thrown into a field about 100 yards off. The driver escaped with slight injury.

THE Lemberg-Czernowitz-Jassy Railway Company have notified the opening of another portion of the line from Suczawa to Roman, the first section to Moldavia, thus shortening the approach to the Black Sea by 108 kilometres, without taking into account the Paskain-Jassy line, which the company expect likewise to complete by the end of this year simultaneously with the Russian works from Tiraspol (Bender) to Kischeneff. The approaches to the ports of the Black Sea (Odessa) will then, it is stated, be from Jassy to the Pruth 17, and thence to Kischeneff 107, total 124 kilometres, thereby connecting the Black Sea with the Baltic in one direct route, *via* the Lemberg-Czernowitz-Jassy line.

ACCORDING to official statistics, 858 accidents occurred on Prussian railways in 1867. The train ran off the rails 206 times, there were 68 collisions, 432 times the carriages or engine were injured, nine persons travelling on the train were killed, and 21 in other ways, while 68 were more or less seriously injured. The causes of the accidents were as follows:—124 arose from the state of the atmosphere (snow, fog, wind, &c.), 25 from accidental obstacles on the line, 4 from obstacles intentionally placed there, 11 from the carelessness of officials, 60 from the mistakes of engine-drivers, and 41 from the bad state of the line. The rest were the results of faults in the locomotives, carriages, &c., or of undiscovered causes.

AT a meeting of the Royal Botanic Society, held at the Gardens last Saturday, Mr. James Heywood in the chair, a letter was read from H.S.H. the Prince of Teck, president of the Society, nominating the following members of the council to be vice-presidents during the ensuing year:—The Duke of Buckingham and Chandos, K.G., Marquis of Bristol, Lord Calthorpe, Lord Chesham, Lord Tredegar, Lord Alfred Hervey, Bishop of Oxford, Sir W. Stirling, Bart., the Right Hon. Sir William Hutt, K.C.B., Charles Robert Turner, Esq. Seven new fellows were added to the Society, and the chairman read a list of dates as fixed for the exhibitions and fetes, promenades, lectures, and other meetings for the next season.

THE often-sought-for site of the Roman city of Trajanopolis has recently, it is said, been discovered. The remains have been found in an extensive marshy district near Enos, a league and a half from Dymes, at the mouth of the Hebrus. To the unhealthy nature of this region is attributed the fact that the ruins of such a large city have remained so long undiscovered, few travellers caring to incur the risk of catching a fever or ague by traversing it. That these are really the ruins of Trajanopolis is supposed to be proved by an inscription found on a stone built into a monument erected by the Romans, and on their situation being in exact accordance with the position assigned to the city in ancient books of travel.

THE value of our exports to the Australasian group of colonies has experienced a considerable increase this year, having been £8,649,983 for the eight months ending August 31, as compared with £7,294,843 in the corresponding period of 1868, and £5,850,875 in the corresponding period of 1867. Every one of the seven Australasian colonies has been a larger consumer of our goods and products this

year—a very gratifying circumstance. Annexed is the value of the exports made to each of the seven colonies to August 31 this year:—Western Australia, £81,046; South Australia, £946,120; Victoria, £4,002,835; New South Wales, £2,147,419; Queensland, £263,306; Tasmania, £179,862; and New Zealand, £1,029,395.

THE following is a method given by M. Weiszkopf of producing upon iron a durable black shining varnish:—Take oil of turpentine, add to it, drop by drop and while stirring, strong sulphuric acid until a syrupy precipitate is quite formed, and no more of it is produced on further addition of a drop of acid. The liquid is now repeatedly washed with water, every time refreshed after a good stirring, until the water does not exhibit any more acid reaction on being tested with blue litmus paper. The precipitate is next brought upon a cloth filter, and, after all the water has run off, the syrupy mass is fit for use. This thickish magma is painted over the iron with a brush; if it happens to be too stiff, it is previously diluted with some oil of turpentine. Immediately after the iron has been so painted, the paint is burnt in by a gentle heat, and, after cooling, the black surface is rubbed over with a piece of woollen stuff dipped in and moistened with linseed oil. According to the author, this varnish is not a simple covering of the surface, but it is chemically combined with the metal, and does not, therefore, wear off or peel off, as other paints and varnishes do, from iron.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1628, 1646

BUILDINGS AND BUILDING MATERIALS—1588, 1603, 1612, 1622, 1623, 1636

CHEMISTRY AND PHOTOGRAPHY—1638

CULTIVATION OF THE SOIL, including agricultural implements and machines—1575, 1634

ELECTRICAL APPARATUS—1600, 1627

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1580, 1591, 1635, 1644

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.

FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments, &c.—1571, 1574, 1583, 1597, 1610, 1619

GENERAL MACHINERY—1594, 1602, 1604, 1609, 1615, 1616, 1647

LIGHTING, HEATING, AND VENTILATING—1572

METALS, including apparatus for their manufacture—1573, 1575, 1577, 1582, 1586, 1593, 1626, 1641

MISCELLANEOUS.—1576, 1579, 1585, 1589, 1592, 1595, 1599, 1605, 1611, 1620, 1629, 1630, 1631, 1632, 1637, 1642

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1581, 1584, 1590, 1601, 1607, 1608, 1618, 1625, 1639, 1640, 1643, 1649, 1650

SHIPS AND BOATS, including their fittings—1587, 1624, 1648

STEAM ENGINES—1596, 1598, 1606, 1614, 1621, 1645

WARFARE—1613, 1633

1571 E. H. PULBROOK, Tooting. *Organs.* Dated May 21, 1869.

Hitherto in organs where the keys are placed at some distance from the instrument motion has been communicated to the pallets from the keys by means of levers or rods, known as trackers, or by electricity. Now, according to this invention, the inventor connects the pneumatic apparatus at or near the keys with the pneumatic apparatus in the instrument and in connection with the pallets by means of a tube or tubes.—Patent completed.

1572 W. H. DUPRE, Jersey. *Light and ventilation.* Dated May, 21 1869.

This consists, first, in simplifying the form and construction of roof lights, having for its object a more effectual method of inserting the glass within the valve frame, through the medium of a rabbet or slider fitted with a hinged beading in which the glass is enclosed, and protected on all sides in conjunction with square or round corners forming the base or bottom plate to the roof lights. Second, in the employment and mode of opening and closing pane ventilators by means of sash weights and cords applied thereto, by which it is opened and shut as required, and fitted with wire gauze at the top of same for the exclusion of dust, insects, or otherwise.—Patent completed.

1573 A. MUNRO, Arbroath, and W. B. ADAMSON, Glasgow. *Treating metallic substances.* Dated May 21, 1869.

This consists in casting the metals or their alloys or articles composed thereof into chills of the required shape and dimensions. The metals or their alloys, or articles composed thereof, are by the chill rendered very dense, hard, and brittle, and the present invention consists in placing the substances or articles composed thereof in open or closed vessels or boxes containing carbonaceous matter, the vessels or boxes so filled being submitted for a variable length of time to heat in a closed or open furnace, retort, kiln, or oven, or in place of using carbonaceous matter alone, other substances, such as calcareous matter, may be admixed with it.—Patent completed.

1574 J. PLATT, Birmingham. *Brooms and brushes.* Dated May 21, 1869.

In preparing the knots or bunches of the brushing material for securing into the stocks or backs of brooms or brushes, the inventor cuts the brushing material into suitable lengths, and ties such lengths in the middle; the lengths so held are then doubled or bent up. The inventor takes a stock, back, or board, whether flat, bevelled, round, oval, or other required outline, and formed of wood, metal, ivory bone, shell, composition, or other suitable material, and drills or bores to a requisite depth upon the brush surface a number of round or other shaped holes in the ordinary manner. These may be arranged in straight rows at angles to each other, or in a suitable pattern for receiving the knots or bunches of the material to form the broom or brush.—Patent completed.

1575 C. W. SIEMENS, Great George-street, Westminster. *Calcining and smelting ores.* Dated May 21, 1869.

This consists chiefly in effecting the calcination of metallic ores, and also the burning of such substances as cement, lime, or plaster of Paris, on a drum or cylinder of iron, lined with hollow firebrick, forming longitudinal channels, which is mounted upon rollers and is made to rotate round its horizontal axis.—Patent completed.

1576 A. M. CLARK, Chancery-lane. *Opening eggs.* (A communication.) Dated May 21, 1869.

This apparatus consists essentially of a cutter having a circular motion which embraces and makes a circular incision round the end of the egg which is required to be removed.—Patent abandoned.

1577 W. R. LAKE, Southampton-buildings. *Shearing and punching metal.* (A communication.) Dated May 21, 1869.

This relates mainly to a peculiar combination of levers, which are adapted to effect the operations of shearing, punching, and bending iron and other metals, shrinking and stretching tyres, and "gumming" or cutting between the teeth of saws. In this machine the levers are arranged in combination with a cam, and all of the parts are mounted upon a strong frame.—Patent completed.

1578 C. J. FOSTER, Maldon. *Reaping and mowing machines.* Dated May 21, 1869.

In order to produce the reciprocating motion of the cutter bar the internal periphery of the motor wheel is provided with a flange consisting of a continuous zigzag with curvilinear bearing surfaces. This flange is to be cast in one with the rim and spokes, and, consequently, the wheel is immensely strengthened, and rendered capable of sustaining sudden strains without risk of fracture.—Patent completed.

1579 N. LAWRENCE, Great Prescott-street, Goodman's-fields. *Lighting cigars.* Dated May 21, 1869.

The lighting end of a cigar is to be dipped into a fusee composition, specially prepared of gum arabic, 20 parts; chlorate of potash, 10 parts; nitric, 40 parts; charcoal, 20 parts; and cascarita, 16 parts. When dry, the inventor dips the cigar a second time into a safety composition, consisting of gum or glue, 3 parts; chlorate of potash, 10 parts; powdered glass, 1 part; and antimony, 1 part. Safety friction is composed of gum, 1 part; and amorphous phosphorus, 2 parts; which is placed on a paper or label, and wrapped round the cigar. The label is easily removed by slipping it off, and by bringing the friction, which is placed on the label, in contact with the dipped end of the cigar, the latter is ignited.—Patent abandoned.

1580 J. HUDSON and C. CATLOW, Burnley. *Looms.* Dated May 21, 1869.

The inventors place on the shaft of the emery roller a boss having two arms extending therefrom. Supported by the arm nearest the sley is a tension bar or roller; to the other arm is attached a link or spring extending to the shaft of the cloth roller and resting on the ordinary weight lever. The cloth passes over the breast beam, over the emery roller, and over the extension bar or roller to the cloth beam. The cloth passing over or from the emery roller to and over the tension bar or roller (placed nearest the sley as described) has a tendency to bind the emery and cloth rollers together, stretching the cloth and winding the cloth hard or tight on the beam.—Patent completed.

1581 W. MORRIS, South Hackney. *Connecting railway rails.* Dated May 21, 1869.

The inventor connects and secures the ends of rails together, simply by fitting to the sides of such rails at the end parts thereof fishes, or securing pieces formed so that they shall fit into the web of the rail, that is, between the enlarged parts, such fishes or securing pieces having grooves formed in them for the purpose of fitting into corresponding dovetail projections on the sides or web of the rail at the end part thereof, and when this fitting is effected on both sides of the rail, the same will be thereby secured without the aid of screw bolts and nuts.—Patent completed.

1582 H. R. LUMLEY, Marlborough-place, N.W. *Treating crude iron.* Dated May 22, 1869.

When melted, the inventor causes iron to be run into a converting vessel, so prepared that the molten metal may fall through suitable apertures, and from a sufficient height, in the form of a shower of minutely subdivided streams or particles, through an upward current of cold or heated air. The iron is then taken from the vessel suitably prepared to receive it, and is hammered or otherwise treated according to the ordinary methods used in preparing malleable iron and steel.—Patent abandoned.

1583 R. ORLEY, Axminster. *Invalid bedsteads.* Dated May 22, 1869.

This consists in fitting and supporting a false sacking or bottom, or the frame in which the sacking or bottom is connected, by means of cords to the four posts of the bedstead. The cords pass over pulleys, and lead to a transverse shaft or roller placed under the bedstead. This shaft or roller is actuated by a bevel or a worm and pinion arrangement, worked by a crank handle or otherwise at the foot, head, or side of the bedstead. A catch or other appliance may be fitted to hold the false sacking at any required height. By detaching the cords at the head or at the foot, any inclination can be given to the false bottom.—Patent completed.

1584 J. LOCKWOOD, Leeds. *Railway couplings.* Dated May 22, 1869.

This consists in applying to the draw bar, or in constructing them with, catches or hooks capable of taking into each other in a lateral or sidewise direction, the slot holes in the framework of the engine, carriage, or waggon being made so as to allow for lateral deflection or motion of the draw bar. These catches or hooks are made of sufficient breadth or depth to provide for the difference in height of the draw bars of different carriages from the rails.—Patent abandoned.

1585 E. T. HUGHES, Chancery-lane. *Horseshoe nails* (A communication.) Dated May 22, 1869.

A bar of iron, the size of the nail head, is passed through a pair of rollers which reduce it at certain places to form a blank of the proper size for the subsequent operations of making the nails.—Patent completed.

1586 G. T. BOUSFIELD, Brixton. *Casting iron.* (A communication.) Dated May 22, 1869.

This consists in the combination of a spout for delivering the molten iron with a series of removable box moulds, by means of a traversing mechanism, consisting of a revolving table or chain, or some equivalent or substitute therefor, which operates to traverse the series of box moulds in succession beneath the spout, so that each box mould in succession can receive a portion of the molten iron. When the box moulds are filled, each may be removed separately and successively by a crane and reversed, so as to drop out its contents, and may then be immediately replaced by the crane in its position upon the traversing mechanism.—Patent completed.

1587 J. H. DAVIS, Cape Town. *Ships' compasses.* Dated May 22, 1869.

The compass bowl is made of an oval form, and is mounted on gimbals; in the bowl two floats are placed. They are floated on water or other liquid, and are kept in their places by central pivots, or the pivots may form the entire support. The two floats are geared together by means of teeth or otherwise, in such manner that they turn simultaneously but in opposite directions. On one of the floats a number of magnetic bars are fixed parallel the one to the other.—Patent abandoned.

1588 M. TILDESLEY, Willenhall. *Sash pulleys.* Dated May 22, 1869.

The inventor casts the pulley frame for receiving the bowl in two counterparts or halves, that is to say, one of the side cheeks and half of the width of the face plate to each casting. Upon one of these castings are formed the pins or rivets for securing the two parts together, and in the other casting are formed the pin or rivet holes, while in the cheeks are cast the bosses, countersinkings, or holes for the axle of the pulley bowl to work in.—Patent abandoned.

1589 S. THOMAS, jun., Redditch. *Needle wrappers.* Dated May 22, 1869.

The inventor cuts or stamps out of paper or other suitable material the form shown in the drawings annexed to the specification filed. The flap part of this is then folded up; the needles which are to be wrapped up in the envelope, having been stuck in the usual manner upon cloth or other suitable material, are placed upon the part, and the flap or tail piece folded down over the loose end of the cloth upon which the needles are stuck, so as to prevent their displacement, and to keep them in one position in the wrapper: the part having in it the slit is then folded down upon the needles, and a second part folded down upon a third, the tongue or tuck being inserted in the slit.—Patent completed.

1590 W. H. BLISS, Bayswater. *Velocipedes.* Dated May 22, 1869.

Three wheels are employed in combination with curved or other suitably formed springs, which are mounted upon the axle of the two hind wheels, such spring or springs being combined with a central spring attached to the longitudinal beam or body of the velocipede in front.—Patent abandoned.

1591 L. J. CROSSLEY and R. HANSON, of Halifax. *Steaming yarns.* Dated May 22, 1869.

In order to prevent the various colours applied to the yarns from spreading or running into each other, by reason of the water or moisture arising from the condensed steam settling upon the yarns, the latter are placed in a chamber to which steam is admitted, and which is surrounded by a jacket containing steam of a somewhat higher pressure and consequently hotter. Another important advantage of the jacketed chamber is that the steam used in the setting process is greatly economised, as the inventors are able to reduce the size of the chamber by dispensing with the sloping or angular roofs heretofore used in steam chambers, and which were designed to prevent the condensed steam which gathered within on the under side of the roofs from dropping on to the yarns.—Patent completed.

1592 W. FURNESS, New-street, E.C. *Fastening for belts* Dated May 24, 1869.

The clip or fastening consists of two metal jaws hinged together in any suitable manner, each jaw being provided on its internal or biting edge with a series of serrated teeth or other gripping edges. The opposite side of each jaw is curved or otherwise bevelled off to suit the curvilinear line of the belt or strap on which it is intended to bear.—Patent completed.

1593 W. MITCHELL, Manchester. *Grinding metallic articles.* Dated May 24, 1869.

This consists in applying to the periphery of a revolving disc made of metal, wood, or other suitable material, a continuous stream of sand and water, which is contained in a vessel or receptacle, from which it is caused to flow through an opening or valve during the time the disc is revolving, the valve being closed and the flow of sand and water cut off during the time the disc is not in motion.—Patent completed.

1594 B. F. WEATHERDON, Chancery-lane, *Reacting turbine wheel.* (A communication.) Dated May 24, 1869.

This consists in employing (in connection with the Scotch system of turbines) an outer wheel or case mounted upon the same axis, so as to receive the repellent action of the water issuing from the discharging orifices thereof, and cause the same to turn in a contrary direction to the turbine, and communicate motion and power thereto through the medium of a tooth and pinion and shifting slide-valve gear.—Patent completed.

1595 W. A. GILBEE, South-street, Finsbury. *Ice houses.* (A communication.) Dated May 24, 1869.

The inventor constructs an ice house with a close ice chamber, from which the external atmosphere is excluded. The devices he employs for abstracting and removing the sensible heat and moisture of the internal atmosphere of a close ice chamber mechanically consist of a corrugated sheet metal ceiling and wooden gutters suspended under it, constructed with discharge pipes.—Patent completed.

1596 M. H. DE GOESBRIAND, Paris. *Steam motors.* Dated May 24, 1869.

This machine may be compared to a turbine moved by steam in lieu of water, the motor being enclosed within the condenser. Two pumps serve for injection and extraction, the extraction pump is worked by the same crank as the injection pump, and like it is a suction and force pump. It sends the condensed steam directly into the boiler.—Patent completed.

1597 E. T. HUGHES, Chancery-lane. *Manufacture of brushes.* (A communication.) Dated May 24, 1869.

First, the table of the machine is arranged upon a universal joint on the spindle or bracket so as to be adjusted to present the brush back to the bit or tufting apparatus. Second, the holder of the machine is perforated or indented, according to the design of the brush to be produced, so as to be adjusted upon the point on the table.—Patent completed.

1598 G. SALT, Saltaire, York, and W. INGLIS, Bolten. *Steam engine governors.* Dated May 24, 1869.

A weight is applied by means of a bell crank lever directly to the rod, by which the action of the governor is transmitted to the lever of the cut off gear. The rod is connected by a coupling piece to the bell-crank lever of the governor. This coupling piece is fitted with a pair of clips, whilst the end of the rod is fitted with a disengaging toe, lever, or trigger, like the valve rods of a small kind of liberating valve gear. The trigger is connected by a link to a lever, which is adjustable by hand, the parts being shown in the positions in which they are when ready to act. Then should the rotation of the governor cease from any cause, the consequent descent of the balls will first cause the rod to be moved over towards the cylinder, which will be in the direction corresponding to an increased supply of steam, but this action will be only momentary, as on the rod being moved a certain distance, the trigger will effect the disengagement of the two parts of the rod, and the weighted lever will immediately move the part away from the cylinder, and thereby adjust the valve gear so as admit no steam.—Patent completed.

1599 A. BARCLAY, Kilmarnock. *Injecting and ejecting liquids.* Dated May 24, 1869.

This consists in using a more numerous series of nozzles than have hitherto been employed in injectors or ejector condensers, and in constituting them a compound nozzle. The invention also consists in placing a stopcock or valve in the passage connecting two of the branches or passages in the instruments or apparatus constituting the injectors, ejectors, or ejector-condensers, so that the branches may be put in communication with each other or their communication cut off.—Patent completed.

1600 J. BRITTAIN, Bowling Green-lane. *Telegraphic instruments.* Dated May 24, 1869.

The inventor inserts in an inking trough a wheel, the periphery of which, by preference, he notches that it may the better, while being rotated, lift the ink, and present to the pen or marker a continuous supply.—Patent completed.

1601 R. RICHARDSON, Great George-street. *Velocipedes.* Dated May 25, 1869.

The inventor places the wheels one behind the other, but not in the same plane, and arranges the seat or seats so that the load, instead of having to be balanced unstably upon the one line in which the wheels as at present arranged touch the ground, is supported upon and between the parallel lines in which the wheels run.—Patent abandoned.

1602 J. DICK, Coatbridge. *Rolls for rolling mills.* Dated May 25, 1869.

This consists in forming such rolls hollow, in place of solid as hitherto, so that the rolls may be kept cool by allowing water or other liquid or fluid to flow through them.—Patent completed.

1603 J. H. JOHNSON, Lincoln's Inn-fields. *Imitation of wood.* Dated May 25, 1869.

The inventors takes any kind of fibrous vegetable, animal, or even mineral matter, such for instance as flock paper, leather chips, or asbestos, and reduces the same to a very fine state, so that the particles can be intimately and thoroughly mixed with a pulverised cementing or agglutinizing substance. This cement he thorougly intermixes with the fibrous substance, both being in as dry a state as possible.—Patent abandoned.

1604 J. TROTMAN, Painswick. *Fastenings for driving bands.* Dated May 25, 1869.

This consists in uniting the ends of machine driving bands or straps by means of two plates of metal screwed together with the ends of the strap between them.—Patent abandoned.

1605 W. JONES and T. SHEFFIELD, Manchester. *Drawing instruments.* Dated May 25, 1869.

This consists in providing the straight edge or rule to be employed as a guide for the form of line required with a groove or channel running parallel to and near the straight or curvilinear edge of the rule or guiding piece.—Patent abandoned.

1606 F. T. BLAKE, Boulogne. *Motive power.* Dated May 25, 1869.

This consists in the combination with a series of gravitating weights sliding along arms or radial guides, in a rotary wheel or disc, mounted on a shaft of a stationary guiding surface, which acts upon the weights in such a manner as to move outwards from the centre of the revolving wheel or disc, a sufficient number of the sliding weights to overcome the counteracting gravity and leverage of the remaining weights, which latter are simultaneously moved inwards towards the centre again by another portion of the same guiding surface.—Patent abandoned.

1607 G. H. HOARE, Southampton-row, W.C. *Velocipedes.* Dated May 25, 1869.

Instead of placing the wheels of bicyles in a line one before the other, the inventor places one wheel at a little distance on one side and the other at a little distance on the other side of the central line, by which means a bicycle or velocipede is enabled to stand by itself without any other support. The two wheels are connected together by a light iron or steel bar or frame, having fixed thereto a spring seat, or saddle, as usual, and instead of driving by means of cranks or treadles fixed directly to the front wheel, the inventor mounts the cranks or treadles upon a grooved wheel, placed intermediate of the bearing wheels, motion being communicated to one of such wheels by a gut or band passing around the grooved wheel.—Patent abandoned.

1608 A. M'NEILE and J. SLATER, John-street, Pentonville. *Carriage wheels.* Dated May 25, 1869.

This relates more particularly to cast or wrought iron axle boxes or naves. One of the principal objects of the invention is to so construct the felloes of wheels that should a part of the felloe of one or more of the spokes become damaged, such damaged part or parts may be removed and repaired, or new parts substituted, with greater facility than can be done with wheels of the ordinary construction, and without the necessity of removing the whole or greater part of the felloe.—Patent completed.

1609 L. ROMAN, Paris. *Hydraulic motive power.* Dated May 25, 1869.

The apparatus consists in two or more endless chains provided with curved or straight paddles, which latter are kept perpendicular and parallel to each other at suitable distances apart, so as to form an endless chain of paddles, which is carried over two or more octagonal drums, wheels, or pulleys, the axes of which are situate parallel to the level of the water, and revolve in vertical standards provided in boats or suitable movable or fixed supports. The endless chain is laid in the direction of the current, and kept at such a height that the paddles of the lower portion of the chain are immersed perpendicularly in the water, whilst the remainder of them are out of this latter; the current in acting on the immersed paddles will carry them forward, and thus cause the revolution of the endless chain, and also the revolution of the wheels, drums, or pulleys, over which this latter is carried, which motion may further be transmitted by any suitable mechanical means to and serve as a motive power for driving machinery or other similar purposes requiring a cheap and efficient motive power.—Patent completed.

1610 R. WHEBLE, Cockspur-street. *Hats.* Dated May 25, 1869.

This consists in the application to the ordinary brim or border of the hat or to the hat body of a supplementary or movable brim of any size or form required, such brim being attached to the ordinary brim or to the body of the hat by any suitable fastenings capable of being adjusted and removed, according to the brim required to be applied and worn.—Patent completed.

1611 R. SCHOMBURG, Fleet-street. *Tobacco ash receiver.* Dated May 25, 1869.

This consists of an apparatus for receiving and discharging cigar and tobacco ashes in railway and other carriages, which consists of a trough turning upon centres in a suitable framework to be attached to the carriage. This framework is open on the top and on one side, the ends and back and the bottom forming the closed casing. The trough receives the ashes, and by turning a button or other contrivance at one end the trough discharges its contents on the outside, and after doing so resumes its former position.—Patent abandoned.

1612 M. BENSON, Southampton-buildings. *Glass cutting tools.* (A communication.) Dated May 26, 1869.

This consists of a tool composed of a disc and made to revolve on its axis as it is passed or drawn over the surface to be fractured or cut.—Patent completed.

1613 W. PALLISER, Pall Mall. *Vents and screw nuts for ordnance.* Dated May 26, 1869.

This consists in making the lower end of the vent separate from the upper part, and composed, by preference, either of platinum or of an alloy of platinum and iridium, which separate lower portion the inventor screws in from the inside of the gun, making it fit with a countersunk head into a corresponding recess in the gun; the upper end of this lower portion of the vent fits into the recessed end of the upper part of the vent, which is screwed in from the outside, and is formed either entirely of copper or of steel or iron with a lining of copper screwed in from the lower end. The improvements in screw nuts or collars for securing the tube or lining of the patentee's converted or compound guns consists in forming the bearing surfaces either of the screw thread or of the nut or collar with such an incline that, in being screwed up, they shall exercise a wedging action sufficient to prevent the nut or collar from unscrewing through the jarring effect produced by firing, and at the same time to produce an accurate and tight fit between the tube, the nut, and the casing, and thus neutralise the effect of vibration, which is apt to crack the tube if loose in the muzzle of the gun.—Patent completed.

1614 H. D. M'MASTER and A. DALE, Gilford, Ireland. *Engine governors.* Dated May 26, 1869.

This consists in the use of a force pump of any suitable construction in connection with a cylinder and ram for regulating the motion of steam engines.—Patent completed.

1615 T. VAUGHAN and E. WATTEEU, Middlesborough-on-Tees. *Nutting screw bolts.* Dated May 26, 1869.

The inventors arrange two vertical opposite discs a certain distance apart, but connected together in an adjustable manner so as to regulate their distance apart to the length of the bolts to be nutted, for which purpose a central cylinder in the one disc fits into a central recess in the other, which cylinder is capable of being made to slide in the recess by means of an adjusting screw. The disc having the recess is of considerable depth, and is made to revolve slowly in bearings formed in a fixed framing carrying with it the second disc, rotary motion being imparted by a spur pinion in gear with a spur rim fixed to the first disc, and receiving motion through speed reducing gearing from a driving shaft carrying a fast and loose pulley.—Patent completed.

1616 W. TATHAM, Rochdale. *Doffing the sliver from carding engines.* Dated May 26, 1869.

The inventor places a fan, revolving at a moderate velocity, directly over the doffer or other cylinder, of the width of the cylinder, and blows the material from it in a dispersed condition, and collects it either as and for the purpose stated in the provisional specification of a patent for which protection was granted to him on January 8, 1869 (No. 57), or he blows it against a travelling creeper, moving at such rate as to be thereby conveyed in sliver form to delivering rollers in the usual manner.—Patent abandoned.

1618 J. D. BRUNTON, Leighton-crescent, N.W. *Tunnelling.* Dated May 26, 1869.

The inventor substitutes for the revolving discs or for the sectors having bevelled cutting edges, a row or rows of cutting tools of a chisel form, and he acts upon these chisels by rollers or rotating discs, so as to cause them to chip pieces off the rock or stone. The chisels may be so placed or arranged side by side in a row or rows as that their edges shall form a circle either concave or convex, or so that their edges shall form a straight line or any other figure that may be desired.—Patent completed.

1619 C. F. CHEW, George-street, N.W. *Pianofortes.* Dated May 26, 1869.

This consists in the use of a pin formed with a collar. This pin passes through a hole in a metal plate, and has a screw formed on its lower part to receive a nut, between which and the metal plate the inventor places a washer of leather or other available material, as well as an iron washer, and when the string is drawn to the desired pitch by the turning round of the pin the nut is then screwed up, and thus keeps the pin from removing, and retains the tension on the string, whereby the instrument keeps in tune for a much longer time.—Patent completed.

1620 J. J. FIELD, Highgate. *Microscopic apparatus.* Dated May 26, 1869.

This consists in a frame (which fits below the object stage) and carries a Nichol's prism (or other polarizer) at the lower, and a certain number of thin plates or films of selenite at the upper part of the apparatus. The selenite films or plates are arranged in cells of different diameters, which cells admit of rotation, and are toothed around their circumference, and they gear into toothed wheels (also of variable size) fixed on an upright pillar near the side of the apparatus. The pillar wheels (which may be called the drivers) are so attached that they can only move in unison, and thus when the drivers are moved they cause the selenite frames to rotate with different velocities, but always in fixed ratios.—Patent abandoned.

1621 C. HANSON, Huddersfield, and J. BOTTOMLEY, Kirkgate. *Motive power.* Dated May 26, 1869.

The inventor fixes a driving wheel with faced sides on a shaft. On one side of this wheel they fit a solid ratchet and spur wheel, in the last of which they make a rack, toothed, to fit the wheel to work in a parallel motion. On the driving wheel they fix a click, which is kept to the ratchet wheel by means of a spring, this click fitting the ratchet wheel teeth.—Patent completed.

1622 J. CRANSTON, Birmingham. *Glass houses.* Dated May 26, 1869.

In erections of this description of the ordinary kind there must of necessity be a certain amount of waste room or shallow space near to the floor along the sides or ends which cannot be utilised. By this invention the inventor proposes to form these parts into forcing pits, opening from the outside of the building and divided off from the main structure by suitable means, such, for instance, as stepped, shelving, running around or along the sides of the main building to which the forcing pits so formed act as buttresses.—Patent completed.

1623 J. BRIDGES, Ludgate-hill, E.C. *Lever lock.* Dated May 26, 1869.

This is composed chiefly of three metal plates, one of them being the body or dome of the lock, which is raised by a die to a sufficient height to allow the locking or fastening action to slide freely underneath either horizontally or perpendicularly.—Patent abandoned.

1624 G. H. ELLIS, Gracechurch-street. *Boat cleaning machine.* Dated May 26, 1869.

The inventor provides a set of three circular brushes formed upon one stock, and disposes them at a convenient angle on a suitable base or pedestal. The brushes are, by preference, concave upon their surface, and at one end (the highest from the base) he places a sponge or other pad for blocking. At the other end the iron spindle upon which the brushes are mounted goes into and rotates within a socket formed upon the base or pedestal (at the requisite angle) so that the brushes can be drawn in and out at pleasure.—Patent completed.

1625 R. P. WILLIAMS, Great George-street, S.W. *Fishes for railways.* Dated May 26, 1869.

The inventor takes for this purpose a plate of iron or steel of the length of the fish, and he forms in it two longitudinal corrugations adapted to fit to the lower flanges of the rails, one on either side. The plate is then bent along its centre so as to bring the two longitudinal corrugations above mentioned nearly face to face, but allowing room for the bottom flanges of the rails to pass between them. Bolt holes are formed along the two sides of the fish plate beyond the corrugations, and when the fish has been passed over the bottom flanges of the rails as already mentioned, the bolts are inserted through the two sides of the fish, and the web of the rail between them and the bolts being screwed up, draw these parts closely together, and at the same time draw the corrugations together until they adapt themselves closely to the flanges of the rails, the central bend of the fish plate giving the elasticity necessary to allow them to do so.—Patent completed.

1626 F. H. LLOYD, Wednesbury. *Metal tubes.* Dated May 26, 1869.

The inventor first forms a hollow conical ingot by the process of casting, the casting being effected in a mould, the top and bottom of which are closed, with the exception of a hole in each situated axially, and of a size proper to receive a core of cast or wrought iron or steel. The core is a smooth conical bar having sufficient taper to allow of the requisite amount of contraction in the casting. The outside of the mould is made of a conical tube of cast iron, either in one, two, or more parts. The steel is cast through a " gate " or runner at or near the bottom of the mould, and in connection with a second mould or receptacle containing the molten steel from which the gate or runner is fed. After the mould is full the core is released by being driven downwards by a blow from a hammer or otherwise, thus leaving the hollow conical ingot free to contract as it cools. The outer part of the mould is removed from the ingot, and the ingot is reduced in diameter by rolling or forging with or without a mandrel. The hole in the ingot is contracted as the diameter of the ingot is reduced, and allowance is made for this contraction in the size of the core fixed in the axis of the mould. The rolled ingot is sawn into pieces of the required length, and these pieces are then bored.—Patent completed.

1627 E. G. BARTHOLOMEW, Chepstow Villas, Holloway. *Electrical apparatus.* Dated May 26, 1869.
This consists in making use of the tie bars technically called the "stretchers," or of the pieces which perform this function, as conductors of the electric current, and also as supports to which certain portions of the apparatus may be fixed.—Patent abandoned.

1628 L., W., and J. BEESLEY, Dalton-in-Furness, Lancashire. *Boilers.* Dated May 27, 1869.
The invention may be conveniently carried out by attaching or connecting the tapered box to the cross tube usually used in firebox boilers.—Patent abandoned.

1629 J. SNAPE, Aberdare. *Pumps.* Dated May 27, 1869.
This consists in fitting between the plunger or ram and the suction valve, a piston, the rod of which passes downwards through a stuffing box, and has connected to it another piston working in the branch of a bent pipe leading to the out flow and connected by a short connection or valve box to the suction pipe, so that the valves are kept in a state of equilibrium by resting upon columns of water.—Patent completed.

1630 A. EDLMANN, Palmerston-buildings, C.E. *Manufacture of peat.* Dated May 27, 1869.
In converting the peat into charcoal or fuel, the peat, when dug or raised, is placed in a vertical cylinder of suitable size, in which a shaft armed with knives or blades rotates, the cylinder being also provided with similar knives or blades placed laterally, and in passing between or through which the fibre of the peat is thoroughly broken. The bottom of the cylinder is a spiral incline of from 5deg. to 10deg. of pitch, having at the lowest point a porthole or opening through which, in a state of semipulp, the peat passes on to a pair of corrugated, fluted, or toothed rollers on the top of the machine.—Patent completed.

1631 F. S. ANGEL, Hatton Garden. *Advertising tablets.* (A communication.) Dated May 27, 1869.
A sheet of metal is painted or coloured for forming the ground for the design or lettering which may be required; the sheet thus prepared is then placed on lead with the coloured side downwards. It is then stamped or embossed with letters or designs (prepared in hard and suitable metal) which are put together and placed in a frame after the manner of type; the pressure may be produced by hydraulic press or other adequate means.—Patent abandoned.

1632 F. A. BARROW, Glasgow. *Bleaching oils.* Dated May 27, 1869.
This consists in exposing the oil in a shallow and slowly flowing layer or stream to the action of direct sunlight or of diffused daylight.—Patent completed.

1633 D. FOSTER, Sheffield. *Hollow shot.* Dated May 27, 1869.
The inventor so manufactures hollow shot or shell of cast iron that the nose, or that part which is intended to strike and penetrate an object, is chilled, and he so manufactures the other parts of the hollow shot or shell that such parts are not chilled, or are only partially chilled, and have therefore more tenacity and less liability to fracture.—Patent abandoned.

1634 P. WHITESIDE, Fox-street, Liverpool. *Mowing and reaping machines.* (A communication.) Dated May 27, 1869.
The body or main frame consists of a metal tube which extends from wheel to wheel with radial arms to support the gearing, which support prevents trembling and vibration when the machine is in motion. The drive wheels consist of wrought-iron spokes cast in the hub and rim of the wheels, by which means the wheels are lighter and yet stronger than if made all of cast iron.—Patent abandoned.

1635 H. M'E. WARD, Ballymaconaghy, Downshire. *Spinning flax.* Dated May 27, 1869.
The back top feed or retaining roller is divided into separate parts or bosses, one boss for each spindle end or thread. These bosses are mounted loosely on a common shaft so that they may rotate together or independently of each other, in order to allow of any one or more being stopped without affecting the other feeding bosses on the same shaft. Each feeding boss is fitted with a self-acting contrivance for disconnecting it from its shaft whenever the end breaks that it is supplying to the delivery or drawing rollers.—Patent abandoned.

1636 T. BRADFORD, Manchester. *Drying closets and houses.* Dated May 27, 1869.
The inventor constructs an enclosed drying closet of brickwork, sheet iron, or other suitable material, provided with a stove at one or both ends or sides, or underneath in the usual manner, also with a suitable door or doors, and ventilated in the ordinary way or in any other convenient manner. This closet may be made of any required dimensions and of various forms. In the centre or other convenient part thereof the inventor mounts an upright shaft supported by a suitable footstep beneath, and by a top bearing above so that it can revolve, and he attaches thereto either gearing or any other convenient appliance, by means of which it may be caused to revolve either by power or manual labour. To this upright shaft inside the closet he attaches a series of horizontal arms arranged radially one below the other in a spiral form from the top to near the bottom of the shaft in such a manner that when the clothes or other articles to be dried are hung thereon they shall hang clear of the rest.—Patent completed.

1637 O. PLUMB, Commercial-road. *Ratchet brace.* Dated May 28, 1869.
The inventor employs an ordinary handle or lever encircling at one extremity a cylindrical head or centre piece upon the exterior of which is cut a ratchet. Attached to the handle are two pawls taking on to the opposite sides of the said ratchet, and so arranged that by turning a cam either can be thrown out of or into gear with the ratchet, thus allowing the ratchet brace to be worked in either a forward or backward direction. The face of the cylindrical head is provided with an elongated recess for receiving plates or dies with apertures formed therein for the insertion of the butt end of the drill plates with, different sized apertures being used according to the size of the drill to be employed. These plates or dies are prevented from falling out of their places by means of a ring screwed over them on to the face of the cylindrical head or by other suitable means.—Patent abandoned.

1638 H. A. BONNEVILLE, Sackville-street, W. *Carte and portrait box.* (A communication.) Dated May 28, 1869.
This consists of a box with a lid divided into several compartments, of which the size may be increased or decreased by means of movable partitions sliding in grooves in the wall or surface of the sides which form the compartments.—Patent abandoned.

1639 B. T. NEWNHAM, Bath. *Carriages.* Dated May 28, 1869.
The object of the invention is that parts of the carriage may be readily changeable in order to render it capable of carrying a variable number of persons. Supposing the carriage to be a phaeton or four wheel dog cart with front and back seats arranged *dos-a-dos*, the front under part of the body or the "arms" or "body loops" rise high to admit of large fore wheels to turn under them. The front seat, with its back and side rests, and the part for the legs and feet of those who sit there, together with the "dash" leather, is connected to the body by cranked irons or lever arms, so that the part for the feet may at one time rest against and behind the "body loops," when the back of the seat may form also the back rest for those in the back seat. By raising and bringing forward the front seat with the parts attached thereto upon its cranks or lever arms it becomes a driving box raised over the front wheels and the parts which formed the back seat are attached to and fold against the back of the front or box seat.—Patent completed.

1640 J. WILSON, Royal Exchange-buildings. *Wooden railways.* (A communication.) Dated May 28, 1869.
This consists in forming the rail (for the transit of trains, &c.) of blocks of hard wood with the grain on end bolted and fixed by pins to longitudinal bearings in the manner shown in the drawing accompanying the specification. These blocks, when worn, can be replaced easily and quickly. Transverse sleepers are placed at intervals as on the ordinary railroad, and the longitudinals may be either set into these or bolted down on them as required. —Patent completed.

1641 J. WILSON, Royal Exchange-buildings. *Wrought iron.* (A communication.) Dated May 28, 1869.
This consists in making wrought iron from the melted ore as run from the blast furnace. Instead of running the metal into pigs in the ordinary way it is run into ingots, and at the same time a certain quantity of black oxide of sand ore (about 25 per cent.) in a dry state is poured in so that they mix well together.—Patent completed.

1642 J. BRONNER and H. GUTZKOW, Frankfort. *Obtaining anthracen.* Dated May 28, 1869.
In order to obtain anthracen and similar substances out of asphaltos, the inventors distil it in a fitting apparatus, or heat it in an apparatus for sublimation if required by the aid of steam. They convert the anthracen obtained by the above described method, or anthracen otherwise obtained, and those carburetted by hydrogens, which, in their properties, are similar to anthracen, into an oxydized product by means of nitric acid or of bichromate of potassa and acids, for instance, bichromate of potassa and sulphuric acid, or bichromate of potassa and acetic acid, or of acetic acid and nitric acid, or by chlorates; for instance, chlorate of potassa in combination with acics, muriatic acid, for example, or by other substances acting in a similar manner.—Patent completed.

1643 S. and J. PRESTWICH, Farnworth, Lancashire. *Velocipedes.* Dated May 28, 1869.
This consists in forming the wheels for velocipedes with brass, cast, malleable iron, or other metal naves, and with spokes of wood, the metal naves being formed with cavities or holes to receive the spokes, which holes on one side of the nave are arranged midway between the spaces for spokes on the other side, each wheel having two sets of spokes, one set opposite the spaces between the other set.—Patent abandoned.

1644 J. INGHAM and I. BUTTERFIELD, Bradford. *Dressing warps.* Dated May 28, 1869.
This consists in combining and arranging mechanism so that a brush, or a series of brushes, are caused to travel a certain distance upon a slide plate or bed to operate upon the warps, and then drop upon or be transferred to another bed, on which they are returned and again transferred to the first bed, and so on, continuing to travel forward on one bed and back on the other.—Patent completed.

1645 G. J. PEDLEY, Harborne, and H. GRABOWSKI Willenhall. *Motive power.* Dated May 28, 1869.
The object is to produce an improved motive power which may be usefully employed for propelling velocipedes and other such vehicles. It consists substantially in a coiled or helical spring, acted upon by hydraulic pressure, and what is claimed in the combination of the two forces for the purposes.—Patent abandoned.

1646 W. R. LAKE, Southampton-buildings. *Brushes for boiler tubes.* (A communication.) Dated May 28, 1869.
The invention comprises, first, a boiler flue brush, the flexible or brush portion of which is composed of strips or pieces of steel or other metal inserted in the hub. Second, the combination of a metallic-lined tubular hub or base with a steel or metallic brush. Third, the combination with a boiler flue brush of removable end pieces or heads, and a removable centre rod or handle. Fourth, the application to boiler flue brushes of a guard to guide the brush back into the flue after having been pushed through.—Patent completed.

1647 W. R. LAKE, Southampton-buildings. *Bolts and nuts.* (A communication.) Dated May 28, 1869.
The inventor claims in a machine for heading bolts the combination of the dies, acting simultaneously and moved in guides radially to a common centre by means of the levers and cams in combination with the holding dies and the upsetting die, all constructed and arranged to operate substantially in the manner as set forth.—Patent completed.

1648 G. F. GUY, Bury St. Edmunds. *Sheathing for ships.*
The inventor coats all that portion of the ship or vessel which is exposed to the action of the water with zinc amalgamated on its surface with mercury.—Patent abandoned.

1649 T. CLARKE, Ladyfield. *Velocipedes.* Dated May 28, 1869.
The chief feature of the invention consists in placing the weight as far forward as possible in advance of the central line of specific gravity of the driving wheels, at the same time endeavouring to secure a safe and steady balance in descending inclines or passing over inequalities of the ground. Second, the invention consists in the application of a variable reduplicating or multiplying power by means of wheels (either toothed or plain), drums, or pulleys, and a combination of foot and hand power (or foot or hand power separately), and substituting one power for the other at will, according to the nature of the ground travelled over, by which means either a much higher rate of speed than hitherto can be obtained, or an increased tractive power with a diminished speed may be substituted when required.—Patent completed.

1650 B. GARNER, Oldbury. *Axle bearings.* Dated May 28, 1866.
This consists, first, in making the bearings of lignum vitæ or other hard wood, fixed in grooves or depressions in the upper half of the axle box.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated December 7, 1868.

3529 D. Robertson, W. L. G. Wright, and J. More, Glasgow. A new or improved arrangement of apparatus for forcing and projecting liquids and fluids.
3530 S. Lewin, Poole, Dorsetshire. Improvements in elevators for raising and stacking straw, hay, and other similar substances.
3531 H. P. de Meyrignac, Paris, Boulevard de Strasbourg. A tubular apparatus for brushing and wet-rubbing hair.
3532 J. Swift, Ashton-in-the-Willows, near Wigan, Lancashire. Improvements in safety lamps to be used in coal mines, and for other purposes.
3533 G. Dowler, Birmingham, and W. Pursall, Aston, near Birmingham. Improvements in cartridges for breech-loading firearms.
3534 J. Jonas, Fenchurch-street, City. Improvements in means or apparatus for packing and consolidating tea and other substances.
3535 B. J. B. Mills, Southampton-buildings, Chancery-lane. Improvements in means for securing bales of fibrous and other substances.
3536 W. Scott, Hawick, Roxburghshire. Improvements in furnaces.
3537 J. Watson, Montrose, Forfarshire. Improvements in electric telegraph apparatus for continuous printing.
3538 C. Vavin, Boulevard St. Germain, Paris. An improved apparatus for separating metals and magnetic substances from other bodies.
3539 F. A. Harrison, Birmingham. An improved buckle or fastening for braces, belts, and other articles of wearing apparel.
3540 J. Childs, Victoria-street, Westminster. Improvements in the manufacture of bread and biscuits.
3541 J. H. Johnson, Lincoln's Inn-fields. Improvements in crucibles, melting pots, retorts, furnaces, and other articles subjected to an elevated temperature.
3542 C. Wyndham, Southover, near Lewes, Sussex. Improvements in apparatus connected with velocipedes.

Dated December 8, 1869.

3543 E. Edwards, Lincoln-terrace, Willesden-lane. Improvements in photo-mechanical printing, and the reproduction of designs.
3544 J. S. Robertson, Glasgow. Improvements in horse-shoes for frosty or snowy weather.
3545 M. Kolb, Robert-street, N.W. An improvement in screw propellers for the purpose of reducing the slip of the same.
3546 E. Weldon, Sheffield. Improvements in portable apparatus provided with means for carrying and cooking food, for containing and heating liquids, and with appliances for the toilet, and other like purposes.
3547 M. Stell, Hamerton Mill, Leeds-road, Bradford, Yorkshire. Improvements in the trap twisting frame or machinery for twisting or doubling worsted or other fibrous substances.
3548 G. Preston and J. Prestige, Deptford, Kent. Improvements in apparatus for regulating the supply of water to waterclosets and other similar places.
3549 B. F. Stevens, Henrietta-street, Covent-garden. Improvements in the working of glass, and in forming sheets and other articles therefrom.
3550 M. F. Anderson, Priory-row, Coventry, Warwickshire. Improvements in treating sewage, and in the manufacture of manure therefrom.
3551 A. L. Bricknell, Stratford-upon-Avon. Improvements in gates, and in the posts or supports for the same.
3552 A. M. Clark, Chancery-lane. A new or improved mode of ornamenting figured muslin and gauze fabrics.

Dated December 9, 1869.

3553 H. S. Rush, Brockley-terrace, New Cross, Kent. Improvements in railway chairs.
3554 E. Walker, Heckmondwike, Yorkshire. Improvements in gas burners.
3555 W. Johnson, Elms, Sketty, Glamorganshire. An improvement in machinery for pressing wool, cotton, hemp, and other materials.
3556 H. Byk, Leipsic, Saxony. Improvements to refine paraffin and render it white.
3557 W. Tranter, Birmingham. Improvements in firearms.
3558 J. Loader, Upper Clifton-street, Worship-square, and W. H. Child, Worship-street. Improvements in liquid meters.
3559 D. Clayton, Bradford, Yorkshire. Improvements in shuttles.
3560 C. Sipriot, Milan, Italy. An improved apparatus for exhibiting placards, posting bills, and other advertisements.
3561 J. Hamilton and R. Paterson, Glasgow. Improvements in collapsable casks or vessels for containing fermentable and aerated beverages.
3562 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in vices.
3563 J. F. Alexander, New York, U.S.A. Improvements in undulating propellers for steam ships and other vessels.
3564 R. A. Ballou, Massachusetts, U.S.A. Improvements in fire-resisting safes, steam boilers, pipes, or various other articles liable to exposure to heat.
3565 C. A. M'Calla, Northampton-street, Birmingham. Improvements in closing and stoppering bottles, tubes, and other such vessels, and in the means of regulating and measuring the flow of liquids from such vessels.
3566 J. Ballantyne, Tweed Vale Mills, Walkerburn, near Innerleithen, Peebles, North Britain. Improvements in the manufacture of yarns or threads, and in the mechanism employed therefor.

Dated December 10, 1869.

3567 H. Whittaker, Manchester, and W. Bradbury, Prestwich, Manchester. An improved method of connecting the ends of packing hoops or other metal hoops or bands, and for apparatus employed in connection therewith.

3568 H. Kershaw, Laister Dyke, near Bradford, Yorkshire. Improvements in means or apparatus employed when spinning worsted or other fibres.

3569 G. F. Logan, Glasgow. A new or improved means for utilising waste heat and for consuming smoke, which is also applicable for drawing off and consuming noxious gases or vapours.

3570 W. E. Gedge, Wellington-street, Strand. Improvements in velocipedes.

3571 J. Willis, Stockbridge Works, near Sheffield. Improvements in the manufacture of sunshades and umbrellas.

3572 T. S. Sarney, Catharine street, Sheffield. Improvements in the means of fishing or connecting railway rails.

3573 A. M. Clark, Chancery-lane. Improvements in the ornamentation of shell brooches and other articles of this material.

3574 W. Baines, Railway Plant Works, Soho, Smethwick, Staffordshire. Improvements in apparatus for actuating and controlling railway signals and switches, and for working railway turntables.

3575 R. J. Ransome, Ipswich, Suffolk, J. Deas, Glasgow, and R. C. Rapier, Westminster Chambers, Westminster. Improvements in tramways.

3576 W. Yeoman and J. Gilbert, East-street, Walworth. Improvements in shuttle sewing machines.

Dated December 11, 1869.

3577 W. Downing, Sheffield. An improved breech-loading cartridge with lubricating ball.

3578 J. Barnett, Lunar-street, Chelsea. Improvements in fuel for heating and warming, and in non-conducting material.

3579 G. White, Hemingford-road, Islington. Improvements in the apparatus used for steering, controlling, and propelling steam ships and other navigable vessels.

3580 T. Sagar, T. Richmond, and C. Catlow, Barnley, Lancashire. Improvements in looms and healds for weaving.

3581 A. A. Croll, Coleman-street, City. Improvements in the treatment of ammoniacal liquor of gasworks, to obtain therefrom salts of ammonia.

3582 W. E. Newton, Chancery-lane. Improved apparatus for folding printed sheets of paper, and for cutting and folding printed sheets of paper as they issue from the printing machine.

3583 J. T. Parlour, Trinity-terrace, Grosvenor-road, Pimlico. Improvements in machinery, and in the means employed in connection therewith, for raising sunken ships, and other submerged bodies, and for conducting other submarine operations.

3584 E. Simcoe, Harpenden, Wilts. An improved case or portfolio for filing music, and business and other papers.

3585 W. I. Hetherington, Rothesay, Bute, North Britain. Improvements in motive-power engines specially adapted for propelling ships, but which may be employed for other purposes.

3586 T. Moore, Aston, near Birmingham. Certain improvements in knobs for doors, bedsteads, and other purposes.

3587 W. A. Marshall, Canonbury. Improvements in the manufacture of electric telegraph cables, and in apparatus employed therein.

3588 H. and F. C. Cockey, Frome Selwood, Somersetshire. Improvements in steam boilers and in the setting thereof.

3589 W. C. Green, Duck-lane, Edward-street. Improvements in breech-loading firearms.

3590 H. Wilson, Stockton-on-Tees, Durham. Improvements in machinery for cutting timber into laths, strips, flooring, and other boards and pieces, also for cutting metals and other materials.

3591 W. Williams, Mitford-street, Liverpool. Improvements in subaqueous and tunnel communications, such, for instance, as submarine and other railway tunnels, and in generating tidal and hydraulic pneumatic power to be used for such communications and otherwise.

Dated December 13, 1869.

3592 T. Rawsthorne, Preston, Lancashire. Improvements in putting twist into sliver or yarn from the flyer eye to the front rollers of frames for cotton, woollen, or other fibrous substances.

3593 P. Koch, Manchester. Improved machinery for manufacturing untapped nuts intended for screw bolts.

3594 J. and J. Turner, Rochdale, Lancashire. Improved lubricators for steam engines.

3595 H. Watson, Steeton-in-Craven, Yorkshire. Improved means or machinery for smoothing, marking, and oiling bobbins.

3596 G., J., and M. Oldroyd, Spinkwell and Calder Mills, Dewsbury, Yorkshire. Improvements in means or apparatus employed in weaving.

3597 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of, and means for, preserving dead human bodies and animal carcases.

3598 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in machinery or apparatus for sewing or stitching together the numbers or separate parts of a volume in the operation of bookbinding.

3599 E. A. Cowper, Great George-street, Westminster. Improvements in rotary sieves.

3600 P. C. Evans, Brimscombe Mills, Gloucestershire, and H. J. H. King, Glasgow. Improvements in apparatus for feeding wool, cotton, or other fibrous materials to carding or other machines.

3601 A. Barr, Glasgow. Improvements in apparatus for blowing organs.

3602 W. Asquith, G. Booth, and G. Pickersgill, Halifax. Improvements in machinery to be employed for cutting and boring metals.

3603 H. E. Newton, Chancery-lane. Improvements in net machines.

3604 R. J. Carpenter, Old Broad-street, City. An improvement in the manufacture of iron and steel.

3605 J. Gardner, Bootle, Lancashire. An improved mode of cutting veneers.

3606 R. W. Bernard, Kildare, Ireland. Improvements in candle lamps or imitation candles.

3607 J. Livesey, Victoria Chambers, Westminster. Improvements in street tramways, light permanent way, and temporary railroads.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," December 14, 1869.

2314 J. Sharrocks
2316 W. Hosack
2319 J. Pinchbeck
2320 H. Turner

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department. 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, DECEMBER 24, 1869.

THE CONDITION OF BARKING.

THERE are some people who, although they are continually making blunders and committing mistakes, yet never seem to meet with that punishment which their conduct unquestionably merits. Although constantly "coming to grief" they never appear a bit the worse for it. The fact is that these people have a happy knack, happy for themselves at least, of shifting the blame of their offences and misdemeanours on the shoulders of their neighbours. They can always find a scapegoat, and when found, the unfortunate animal pays dearly for the discovery. Undoubtedly, in this world the innocent suffer for the guilty, and their suffering is caused a great deal more frequently by design than by accident. It will be remembered that early in the autumn of the present year the inhabitants of Barking petitioned Government respecting certain nuisances existing in that neighbourhood. These nuisances the petitioners alleged were caused wholly and solely by the discharge of the sewage of the northern part of London into the Thames near the Creek of Barking. The party answerable for the discharge of the sewage is the Metropolitan Boards of Works, and, consequently, the real point arrived at, was to obtain an injunction against that body to restrain them from continuing their operations. It will be seen as we proceed whether or no the petitioners intended to make a scapegoat of that important corporate association. No sooner was the petition duly forwarded to the Secretary of State than the right honourable functionary promised an official inquiry into the matter, and shortly afterwards made his promise good by despatching the Government sanitary engineer, Mr. Rawlinson, C.B., to the scene of action. That gentleman held an open and impartial investigation into all the circumstances of the case, examined and listened to numerous witnesses, and fully tested the truth or falsehood of the various allegations advanced against the Metropolitan Board of Works. His report is now before us, and from its contents an accurate idea may be formed of the sanitary state of Barking, and the causes which led the petitioners to endeavour to shift the blame of such a scandalous condition of affairs from off their own shoulders to those of the Board of Works.

It is an admitted axiom in legal jurisprudence that a petitioner, whatever guise he may adopt, must come before the court with clean hands. How have the Barkingites fulfilled this maxim? We learn from the report of Mr. Rawlinson that "the town of Barking is without local governing powers, is unsewered, contains many cesspools, a sewage-tainted subsoil, and has a defective water supply." Yet, with all this self evidence against them, they petition for relief at the expense of other people. That they have no local government, is partly the fault of the sanitary legislature, but still more their own fault, as any town in which three-fourths of the inhabitants desire it can place itself under the provisions of the Local Health Act, and at once, by application to the Secretary of State, establish a local board and retain the services of the proper number of officers. The conclusion to be arrived at, therefore, is that, whether from parsimonious or other motives, the inhabitants of Barking did not elect to have a local government, but preferred to remain, like the swine in its wallowing, in the midst of their cesspools, refuse, and sewage abominations. Having once ascertained that the town is without an inspector of nuisances and other corporate officers, the rest of the picture given in the report might be readily anticipated. The fault of the sanitary department of the Government lies in the fact that any town, much less one so near the metropolis, should be permitted to remain in so filthy and infected a condition. As might be expected, the Commissioner admits that the Thames is polluted by the discharge of the London sewage combined with the road and street detritus, and the surface drainage generally, but reports that the main channel has not been reduced in depth by any deposits of this nature, as was alleged in the memorial. The allegation respecting the closing of the Barking Creek to vessels of 250 tons for want of water has not been proved to the satisfaction of Mr. Rawlinson. A very strong point in all cases where it is required to prove the pollution of any stream or watercourse, is the death of its finny inhabitants. Indeed, if that fact, together with the circumstance that cattle which once drank of the water refuse to do so any longer, can be "made out," the case is gained for the petitioners, and an injunction is sure to be granted. It was proved during the inquiry that fish had been destroyed by the empoisoned waters of the Creek, but it was an open question whether this was not due to the presence of chemical refuse in the stream, which could not have been the contribution of the Metropolitan Board of Works.

It will be admitted that, to use a common phrase, "it would be no joke" to engage in litigation with the Board of Works. A body that would think nothing of the expenditure of the thousands attending all lawsuits, and particularly one of this nature, would be a formidable adversary. The Commissioner appears to fight rather shy, in his report, of laying any onus upon that body. In one of the paragraphs, he observes, "That an accumulation of mud has taken place, both on the shore of the Thames and at the mouth of Barking Creek, but from what special cause has not been proved." This is neither more nor less than an evasion of the question. If this accumulation has taken place since the period in which the London sewage commenced to be discharged into the river, there can be no doubt in the mind of any reasonable man of the cause of it. While the people of Barking are deserving of the severest censure for the state in which the town is, yet the fact of their perpetrating a nuisance does not give another party the right to add their offensive contributions likewise. It signifies nothing how foul and polluted a stream or watercourse may be, but no one by law can add a single drop of additional contamination to it. The existing polluted condition of a river does not warrant anyone augmenting it. In other words, the culpability of A does not permit B with impunity to be equally culpable. It must be borne in mind that the Metropolitan Board of Works have universally recognised their obligation to purify their sewage before permitting the effluent water to enter the Thames. They assert that up to the present they have not been able to make arrangements for the purpose, but this is a very different affair from ignoring or denying their liability. In fact, without self-stultification, it would be impossible for them to act otherwise. They have objected in the strongest terms against the pollution of the Thames by the discharge of sewage from the towns situated higher up the stream, and it follows that they cannot well continue to pollute the river themselves at a point lower down. When only small towns have been compelled to provide for the purification and utilisation of their sewage, at least a year has been asked and granted to enable the local authorities to make the necessary arrangements. The Board of Works may reasonably, therefore, demand double or treble that time to perfect their plans for the utilisation of the sewage of the metropolis. That the sewage can be utilised, and profitably too, there is not a shadow of a doubt, and Mr. Rawlinson concurs with us in the opinion, which is one we have always expressed. He objects to all the systems of deodorisation and disinfection by chemical re-agents as both costly and, what is more to the point, productive of imperfect and valueless results. Irrigation is the only plan which offers any chance of realising a profit from the utilisation of sewage. There is no doubt some difficulty in obtaining the large area of land required to absorb so enormous a quantity of sewage as that resulting from the drainage of the metropolis, but this is a difficulty only, and not an insurmountable obstacle.

ACCOMMODATION FOR TRAFFIC AT LONDON BRIDGE.

GREATER or less degrees of publicity have been given to a number of schemes for increasing the accommodation for the traffic upon London Bridge, which serves, according to Mr. Haywood's report, a population of nearly a million souls. Notwithstanding the diversion of a great portion of the traffic by the extensions of the Brighton Railway to Pimlico, of the South-Eastern to Cannon-street and Charing Cross, of the London, Chatham, and Dover to Ludgate-hill, the construction of Southwark-street, and the removal of the toll from Southwark Bridge—all which causes should have resulted in greatly reducing the streams of traffic over London Bridge—the contrary has been the case, and the traffic has increased from 13,000 vehicles passing in 12 hours in 1850, and 16,000 in 1860, to considerably over 20,000 at the present time. The crowded state of the thoroughfare along the bridge, especially on the footpath on the east side, is a matter of notoriety, and a cause of great discomfort and even danger to those who have to pass along the bridge on foot, and attention has accordingly been given for some time past to the important question of providing increased space for the accommodation of the traffic. Among the methods proposed for effecting this object, that which first and most naturally presents itself to the mind as the most ready and least costly in execution is that of widening the roadway by removing the present parapets, and providing footways beyond them, to be supported on cantilevers or otherwise, closing in the new footpaths by open parapets, much less massive than those which now exist, and are an important feature in the architectural details, which can scarcely be interfered with without serious detriment to the architectural effect. Several architects and engineers have recommended the extension of the accommodation on the principle referred to.

Another mode of dealing with the work is to widen the bridge from its foundations, on one or both sides, and either in accordance with the present design or by raising lighter superstructures of iron upon the new extended piers and abutments. By the latter mode an elegant design is doubtless practicable, but Rennie's fine work would be lost irrecoverably, a result much to be deprecated. Yet another mode, the most recent we have heard of, has been designed by Mr. T. P. Ivison, C.E., upon the idea of carrying the foot passenger traffic over the vehicular traffic in the manner adopted at the temporary Blackfriars Bridge, but, of course, by a structure of a very different character. By this mode it is proposed to construct a longitudinal platform 25ft. wide and 18ft. high along the centre of the bridge, the platform, of ironwork, to be supported upon groups of Corinthian columns. The approaches would be by four stairs of 13ft. each, for which space would be taken over

the comparatively useless water stairs at the corners of the bridge, which would still be left with 13ft. available for descent to the river. The ascending stairs would enter upon cross platforms, which would afford means of communication between one footpath and another without threading the way amongst the crowded vehicles—no mean advantage to foot passengers who have occasion to cross the road on or near London Bridge. The existing piers of the bridge would, according to this design, be carried up to the height of the proposed footway, this part of the work to be in Portland stone enriched with sculpture. By this plan about 6ft. would be added to the footway, and the two present footways would be thrown into the carriage road, affording space for two extra lines of vehicles. Mr. Ivison has in his proposed design—which we must not be understood as endorsing—adopted the main principle of the steel bridges he has recommended, and of which he has prepared a model, for street crossings by foot passengers.

OUR IRON-CLAD SHIPS.

It has doubtless occurred to many, as it has to ourselves, that up to the present time there has existed a gap in that part of scientific literature which relates to the iron-clad ship question. That gap has been occasioned by the absence of any work containing a connected and comprehensive statement of the whole subject. There has been a difficulty on the part of the public generally in grasping the question in all its multifarious bearings, because they are so multifarious, and because they involve so many profound scientific problems. Moreover, the many phases of the question have been dealt with at so many different times, and under such varying circumstances, as to give a different complexion even to one and the same point. Parliamentary speeches made annually by the supporters of this, that, or the other theory or system; newspaper reports and articles by those whose political opinions, even unwittingly, improve the occasion either for better or for worse; papers read before scientific bodies by authors having individual tendencies to special views—these are the sources from whence information has to be obtained. What wonder, then, if, bewildered and perplexed, some should give up the attempt to realise the whole question in despair? In such a state of things, it is refreshing to find a way out of the complex meshes which circumstances have woven around the subject, and to know that we have a clear and comprehensive statement of all the facts of the question, one in which it is divested of all mystery, and placed before us in a popular and plain-spoken way. And this we possess in the very interesting work on our iron-clad ships* now before us, and with which the public have been favoured by Mr. E. J. Reed, C.B., the Chief Constructor of the Navy. The whole tone and character of the work indicate an honest desire on the part of the author to place the whole matter before his readers in a clear and direct manner, and in this he has succeeded admirably. As he has worked, so he has written—with one single purpose in view, and that, to do his best. Hence we have ships which reflect great credit upon his talent; the more when the essentially transitional character of the times is taken into consideration. Hence also we have a volume which, being written to inform, for fairness and impartiality has not its superior, whilst for intrinsic value upon a special subject it has not its equal.

Having spoken thus strongly of its merits, let us examine a little into the matter it contains, which will soon show that we have not over-estimated its value. We have first a chapter on the varieties of our ironclads, in which Mr. Reed observes that it has often been a matter of reproach that the British navy is composed of such variously built and appointed ships. He, however, goes on to show that the French have particularly distinguished themselves for diversity of design. Russia has gone to greater lengths in this respect than even France, whilst Prussia, Austria, Spain, and America also furnish examples of fleets of very mixed character. Our author proceeds to account for the diverse features in our ships, pointing out the distinction between radical and minor changes, and showing how the latter often result from gradual advance on a settled plan. We then have an interesting summary of the changes which have taken place since the "Warrior" was built, and so many of which have been necessitated by the progress made in armour and guns. Again, the adoption of twin screws and the abandonment of ships of extreme lengths are other causes which have led to variety in construction. But that this variety does not prevent our ships acting together is proved by the trials of Channel squadrons. In the second chapter we have full particulars respecting the armour of our ironclads, as well as details of the armour and backing of French and American ships. The different systems of armour plating and backing are considered, and their merits and demerits pointed out. In the next place Mr. Reed goes into the question of armament. First noticing the armament of the latest wood line-of-battle ships and frigates, he follows with particulars of those of the "Warrior" and other early ironclads. He then proceeds to show the progress made in the gun question during the last ten years, which has resulted in a reduction in the number of guns carried by our ironclads, but in an increase in their power.

Following our author in the order of treatment he has adopted, we next come to a chapter upon the structure of our ironclads. Although these vessels are mostly iron-built they are not all so constructed, and from this chapter we learn the reasons why some are wood-built. These reasons are various, and tend to show that there is a certain amount of value even in wood hulls. It is, however, clearly shown that iron hulls are lighter, stronger, more durable, and—when properly constructed—safer than wood hulls, and, therefore, far preferable. The French, however, for local reasons have not yet discontinued to build vessels with wood hulls. Chapter V. embodies the whole question of the steaming of our ironclads, and into which Mr. Reed has gone at considerable length. In this section we have a large amount of information respecting the steaming capabilities of our ships of war, and the speeds attained by ironclads and unarmoured ships, as well as with some useful comparisons. The speeds of French and American ironclads are also considered and compared. The question of coaling and that of the measured mile trials are gone into in the latter portion of this chapter. The sailing qualities of our ironclads is a matter which appropriately follows the consideration of their steaming, and their performances in this respect are fully and fairly stated in Chapter VI. It is seen from this portion of the work that the capacity for sea-service has not been lost sight of in our ironclads. This is demonstrated by extracts from the reports of the Channel squadron for 1864-66-67 and 68.

The rolling of the ironclads—a question which has been brought much before the public from various standpoints—is considered in the next chapter. Mr. Reed proceeds to point out many erroneous notions which prevail on this matter, and he proves that as a whole ironclads are absolutely steadier than unarmoured ships. The Channel squadron reports already referred to go to show not only that our ironclads do not roll excessively, but that most of them are comparatively steady. The "Hercules" is perhaps the steadiest of all the ironclads; at any rate, she ranks with the best of them. The whole subject of rolling is, however, far from settled, and Mr. Reed suggests the expediency of a series of carefully conducted trials with ships of different types, under varied circumstances of wind and weather, the observations being carefully made and correctly recorded. The three succeeding chapters treat respectively of the dimensions, forms and proportions, and the cost of our ironclads, upon each of which subjects the information afforded is full and complete.

We next come to chapter XI., which is devoted to a full consideration of the turret ship question, which is very fairly discussed. Mr. Reed points out that, although heavy guns can be trained easily through large arcs in turret ships, they can also be worked very easily on the broadside system. The real advantages of a turret system are small port and great training. With reference to the disabling of the turret by the straining of the vessel in a seaway, or by the turret being struck by heavy shot, Mr. Reed observes that this danger does not exist in Captain Cole's system. Here the turret is carried on a set of rollers fixed in a band at the circumference of the turret base, and is simply centred on a spindle. In chapter XII. our author enters upon a description of ironclad rams, and upon a consideration of the general question of ramming. He gives the experience of ramming afforded by American practice in this direction, also the experience gained at Lissa. From this chapter we learn that handiness in the vessel is absolutely necessary to efficiency in a ram, and that qualification is obtained chiefly by moderate dimensions. The various forms of bows are then described and compared, the chapter concluding with some observations on the manœuvering and working of iron-clad rams.

The concluding chapter treats of the conversion of line-of-battle ships into ironclads. Here our author shows that our navy contains several converted ironclads, but he demonstrates that ships completed could not readily be converted in the same way, although they are capable of conversion upon a different principle. Most schemes for conversion have been based upon the principle of turret armament; the "Royal Sovereign," in fact, is an example. The reasons, however, why other vessels have not been converted may be here briefly stated. In the first place, extensive repairs would be required, the hulls would be heavy, and the armour, therefore, inefficient; their speeds, too, are low, their engines worn, and their behaviour at sea would probably be bad. The proposals for turning line-of-battle ships into rigged monitors are objectionable, as the stability of vessels, thus converted, under canvas is extremely questionable. Moreover, this method of conversion does not provide sufficient buoyancy. However, our wooden ships have really constituted a reserve force, that would have been drawn upon if occasion had arisen. The battle of Lissa proved that wooden ships are far from ineffective in engagements where ironclads are present, and there can be little doubt that such vessels, as a reserve, have a special value.

We have thus taken our readers with us through Mr. Reed's last work, and although we have been able only to glance at each subject, yet we have shown what an interesting and important addition our Chief Constructor has made to naval literature. The volume is illustrated by a folding plate, giving views of all our ironclads tastefully arranged in vignette style, and it is also interspersed with wood engravings, which complete the usefulness of the work. We are much pleased with the production, and heartily commend it to public notice, feeling assured that the public will endorse our opinion, and that with them the book will find full favour.

* "Our Iron-clad Ships, their Qualities, Performances and Cost." By E. J. REED, C.B., Chief Constructor of the Navy. London: JOHN MURRAY, Albemarle-street. 1869.

PHOTOGRAPHY.

A NEW ARTIFICIAL LIGHT—TRANSPARENCIES FOR THE MAGIC LANTERN.

A FEW days ago Dr. D. van Monckhoven read a paper before the Photographic Society of London, describing a new artificial light, which he states to be of great actinic power. He said that although magnesium gives such a very actinic light, his audience would be surprised to hear that chromium burnt in a particular way throws off rays of still greater chemical intensity. When dry hydrogen gas is passed through chloro-chromic acid, and afterwards ignited in a current of oxygen, oxide of chromium is produced at a very high temperature and emits light of such extraordinary chemical power that photographic paper blackens under its influence about as quickly as in full daylight. Chloride of titanium burnt in the same way gives similar results, and the flame has a decidedly blue tinge. "Unfortunately," he says, "these chlorides can be manipulated only by persons versed in scientific research, as they become decomposed under the influence of moist gases, and the lamp then emits a considerable amount of vapour, as is the case with metallic magnesium." He found out that the oxides of the metals of the earths, when ignited under the action of the oxy-hydrogen blowpipe, do not give a light so rich in chemical rays as when the oxide is ignited during its actual formation; therefore, the best plan is to subject the chlorides or carbonates of the earths to the fierce action of the flame, the oxide being then formed in the flame itself. Compressed magnesia and zirconia are not so rich in actinic rays as ignited lime. The light patented by Professor Carlevaris, of Genoa, is produced by allowing the oxy-hydrogen flame to play upon a square piece of retort carbon which had previously been saturated with chloride of magnesium and dried. The resulting light is very actinic, but directly the chloride subjected to the influence of the flame is all decomposed, the ignited charcoal throws off a light which is poor in the chemical rays. Dr. Monckhoven found that the most economical way of getting a good actinic light, free from smoke, on the principles just mentioned, was to use a cylinder of very pure carbonate of magnesia (free from soda, baryta, and iron), either alone in a very compressed state or containing titanite of magnesia, obtained by a mixture of chloride of titanium and carbonate of magnesia. The pillars are square at their base, three centimetres in diameter and eight in height; they burn for an hour and a half, and cost less than half a franc apiece. The cylinders are made by purifying chloride of magnesium from every trace of soda, baryta, and strontia, and then precipitating carbonate of magnesia by the addition of carbonate of ammonia. The precipitate is dried at 300deg. Centigrade, and is pressed into little pillars by hydraulic power. To get a light for photographic enlargements, he uses the "blow-through" oxy-hydrogen burner, wherewith common coal gas is used at its ordinary pressure, and a jet of oxygen is blown through it upon the prepared cylinder. He said that after the flame is made to play upon the cylinder "the heat soon indents the pillar, and it is only when a cavity has been formed that the light attains the highest degree of brilliancy; at this stage the hydrogen stopcock is partially closed until the maximum amount of light has been secured. In the luminous hollow the most vividly incandescent particles of magnesia are seen, and these lose their brilliancy as soon as they have become thoroughly calcined, when other particles are made to replace them. At the end of a quarter or half an hour the pillar is raised somewhat, so as to bring a fresh part of its surface into contact with the flame. The stopcocks should not be opened fully until the maximum amount of light is required; for focussing, the oxygen tap should be opened but very little, and the other regulated accordingly." He pointed out that this plan gave a good steady light for the production of photographic enlargements, also that the lens used in enlarging should be made of very white glass, since the greenish tint of most lenses absorbs a large proportion of the chemical rays.

A cheap and very easy method of producing photographic transparencies on glass for the magic lantern has been found out by Mr. W. H. Harrison. No dry plates, toning, or intensification are necessary. When a pyrogallic and citric acid developer is used to bring out any wet plate picture, the colour of that picture is always a tolerably good black. This black colour, however, may be improved by working with a bromo-iodized cadmium collodion containing a larger proportion of bromide than usual, and the result will be the production of pictures of a delicate blue-black colour by transmitted light. A good bromo-iodized cadmium collodion of commerce should be bought, and three or four grains of bromide of cadmium should then be added to each ounce thereof, and allowed to dissolve; the collodion works best if it be then kept a month or two before using. As the proportion of bromide is so large the nitrate bath should be a strong one, and contain about fifty grains of nitrate of silver to one ounce of distilled water. When the plate is sensitised it should be dipped for a minute in another very pure but weak nitrate bath—strength, twenty grains to one ounce, whereby it is covered with a solution which makes the development more manageable. The plate should then be drained, and the picture printed from the negative by superposition, a few folds of blotting paper being placed at the edges between the prepared plate and the negative to prevent them from touching. The source of light should be small and brilliant, and that from a paraffin flame answers very well. At a distance of a foot from such a flame the right time of exposure may vary from one to three minutes. After development fix with cyanide of potassium, and the picture is finished. That there may be no fog in the shadows care should be taken that all the solutions are sufficiently acid.

TELEGRAPHIC NOTES.

ON Tuesday morning, Mr. Hawkshaw, one of the arbitrators appointed by Government to decide on matters relative to the transfer of the telegraph companies, sat at the Westminster Palace Hotel, for the purpose of hearing those of the shareholders of the International and Electric Company interested in the residue of the purchase money to be paid by the Postmaster-General, and for determining the proportion and manner in which such residue shall be distributed to the shareholders of the company in accordance with the provisions of the Act. The Hon. M. Grimston, the chairman of the company, made a statement to the effect that in 1866 the company issued 15,000 shares of £10 each, for the purpose of extinguishing the debenture debts. Those 15,000 shares were allotted to the proprietors according to the different holdings, and nearly all the shareholders took their proportion. The shares were sold at a good premium for the benefit of the company, and as the debentures fell in they were paid off; £8 out of £10 was called up, leaving £2 unpaid. The only question, therefore, which the arbitrator had to deal with was as to what claim the shareholders were entitled to as regarded the £2. It was argued on the one side that the £2 would now be worth £5 had not the Government stepped in, and on the other side it was contended that the £5 would, in the course of time, be worth £8 but for the interference of the Government. Several new shareholders argued their right of compensation on the £2 uncalled, while the stockholders contended that any advantage to be had was due to them. After considerable discussion, the Arbitrator said he had noted all the *pros* and *cons*; but as the question was one of some importance, he should take time to consider before giving his decision. The proceedings then terminated.

The chairman of the British Indian Submarine Telegraph Company has transmitted for publication the annexed letter dated December 13, 1869, from the company's engineers, announcing the completion of their cable, to be laid from Suez to Bombay:—"Sir,—We beg to report that the manufacture of your cable, 3,600 nautical miles in length, was completed at Greenwich on Saturday last, the 11th inst., and we herewith forward you our final daily return of cable manufactured. The manufacture of the outer covering of this cable was commenced at Greenwich on the 23rd of June last; it has, therefore, been exactly 5 months and 18 days in course of manufacture, equal to 147 working days, which gives an average speed of manufacture of 24½ nautical miles per diem. This is probably the greatest average speed of manufacture ever before obtained for such a long and important cable, and it is gratifying to us to be able to state that its electrical condition throughout the entire manufacture has been practically perfect, and we feel that, so far as its mechanical condition is concerned, the cable is well suited for the depth of water and position it is intended for.

"Yours faithfully,
"CLARK and FORDE."

The Malta Correspondent of the "Times" writes under date of Valetta, December 10:—The Telegraph Construction and Maintenance Company's steamer "Hawk," Captain Briscoe, returned on the 7th inst. from Alexandria. She formed part of the flotilla of steamers that successfully traversed the Suez Canal. After replenishing fuel she proceeded on the 8th for England, to bring out the Suez shore end of the Anglo-Indian Telegraph Cable, and meet the expedition which is now on its way out to the Red Sea with the principal portion of the cable, by way of the Cape.

In connection with the transfer of the telegraphs to the Government on the 29th of January, a farewell dinner was given on Saturday evening at the Cannon-street Hotel to Mr. William Andrews, manager of the United Kingdom Telegraph Company, by the officers and staff. A valuable silver epergne, designed for the occasion, with telegraphic emblems, &c., was presented to that gentleman with an address expressing the esteem entertained for him by the whole of the officials.

Mr. A. Brasher, of the Indo-European Government Telegraph Department, writes to say that it has been officially intimated to his department from Constantinople that the Bagdad-Fao line of Turkish Telegraph, which has been interrupted for the last three months, has been provisionally re-established. The repairs, though not quite completed, will, it is believed, admit of permanent re-establishment in about a week.

The following astounding telegraphic feat is reported:—A telegram, dated "Madras, 20th November," actually reached a London firm on Tuesday last, simultaneously with Madras letters of the 23rd November. Thus it appears that the Telegraph Company takes only three days longer than the Post-office.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

ANOTHER REPORTING MACHINE—THE COLOURING MATTER OF EMERALDS.

ANOTHER reporting machine has been brought before the notice of the public in France This instrument is much more complicated than that of M. Gensoul, which we mentioned some time ago, and to our mind is far too much so to answer its purpose. The object is to print a discourse in ordinary characters as it is delivered, which would save all the trouble of transcribing, such as is necessary with M. Gensoul's machine, which, it will be remembered, prints stenographic characters. It, too, consists of a keyboard, something like that of a piano, the keys acting upon branched levers so arranged that the characters are printed in close succession upon a strip of paper which is rolled along by a movement also communicated by the action of the keys. But this machine of M. Bryois is furnished with no fewer than three hundred keys, which print so many syllables representing all the sounds in the French language. To remember the syllables corresponding to all these keys would be no slight effort of memory, while to print them with sufficient rapidity would require no little manual dexterity. To a pianist who could dash off the finale to Weber's concert, Stück, it would be easy enough, and we have known accomplished pianists in the reporters' gallery. But most, we have no doubt, would prefer to use the pen. The stenographic machine we have alluded to might, we believe, be easily adapted for the English language; but it is seldom that verbatim reporting is desirable, and we gain a great deal by having to rely on the reporter's pen and brains.

Precious stones are still objects of study for chemists, the colouring matter of some being yet subjects of dispute. So far as that of the emerald, however, is concerned, the dispute may now be said to be set at rest. On the one hand, it was believed that the colouring matter was a metallic oxide, that of chromium in fact; but Löwy, by

burning an emerald in a stream of oxygen, obtained a good deal of carbonic acid, and hence concluded that some organic substance gave the colour. The researches of Kuhlman and others have indeed shown that organic matters do penetrate the excessively minute fissures in precious stones, and more recently it has been proved by Mr. Sorby that emeralds are sometimes full of cavities containing a liquid. This he conjectures to be the liquid from which the stone has crystallised, the nature of which we do not know, but which is not unlikely to contain a carbonate. M. J. Boussingault has lately analysed the emerald, and found both oxide of chromium and carbonic acid, and from the latter argues the presence of organic matter. But the carbonic acid may be accounted for in another way, while no doubt is left that the colour is given by chromium. The question, however, is of little importance, and does not in the least affect the value of the stones.

THE WILSON SPANNER AND RATCHET BRACE.

MR. WILSON, of Birmingham, whose improvements in small arms are well known to our readers through our columns, has effected some practical improvements in the screw wrench and ratchet brace. We have illustrated these improvements, and at fig. 1 show the spanner, which it will be seen is set with a screw at the back of the jaws. The moving screw is of steel, and from its arrangement is easily and rapidly adjusted to its work. In fig. 2 we show the new single-acting ratchet brace, the advantages of which consist in the improved construction and arrangement of its driving pawl and ratchet wheel, by which greater compactness, strength, and durability are obtained. The pawl being situated in the lever is held firmly to its work, and at the same time is completely protected from external injury, while the ratchet teeth being formed on the side instead of the circumference of the wheel, are equally removed from danger and are stronger and more durable than those of the ordinary construction. The brace shown at fig. 3 possesses, in addition to the improvements above described, the great advantage of being double-acting. It is constructed with double ratchet teeth, pawls, and levers, which, on being moved from and towards each other simultaneously, impart to the ratchet wheel continuous motion, thereby enabling it to effect its work in half the time of a single-acting brace and drill, and hence its adaptability to the working of lifting jacks and other purposes where continuous motion is a desideratum. By connecting the handles and using them as one the brace is rendered single acting. The manifest advantages of these tools combined with their cheapness will ensure for them a wide market. They are manufactured by Messrs. Wilson, Deeley, and Co., 95, Bath-street, Birmingham.

IMPROVEMENTS IN WATCHES.

IN watches and other timepieces acting with a balance wheel and lever escapement, it sometimes occurs that by a greater than ordinary impulse imparted to the balance wheel from any cause the ruby pin after the lever has been moved over into the one position is carried sufficiently far round to cause it to strike the outside of the fork of the lever in the same direction, whereby, as the lever when thrown over is in contact with the one banking pin and cannot therefore yield to such striking of the ruby pin, it sometimes happens that the ruby pin is fractured or the balance wheel or pallet staff pivots broken or bent. Various contrivances have been proposed to obviate these inconveniences, but all have been either too complicated and consequently expensive in their construction, or too uncertain in their action for general adoption. An invention, however, recently patented by Mr. M. G. Cole, of Belvidere House, Bexley Heath, has for its object to provide both an efficient and simple means for preventing the above liabilities. It consists in placing the banking pins at the tail of the lever, and in so forming this tail as to act as a spring instead of making it rigid as heretofore, the spring being sufficiently stiff as in coming in contact with the banking pins to limit the ordinary motion of the lever to the required extent, while it is sufficiently elastic to allow the lever to yield to the second blow of the ruby pin, and to assume its correct position after the ruby pin has passed it. In place

IMPROVED SPANNER AND RATCHET BRACE.

BY MR. H. WILSON.

FIG. 1.

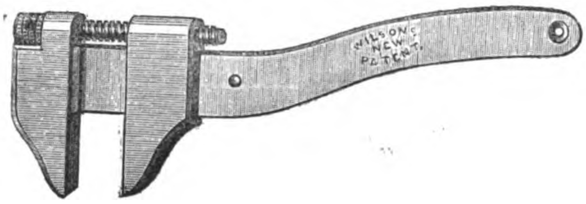

FIG. 2.

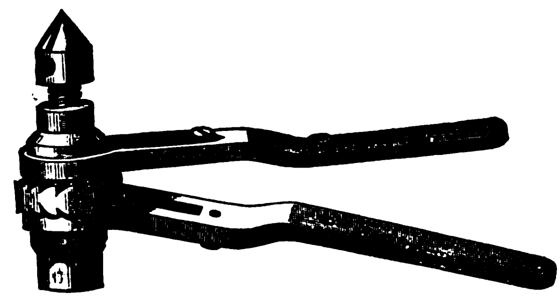
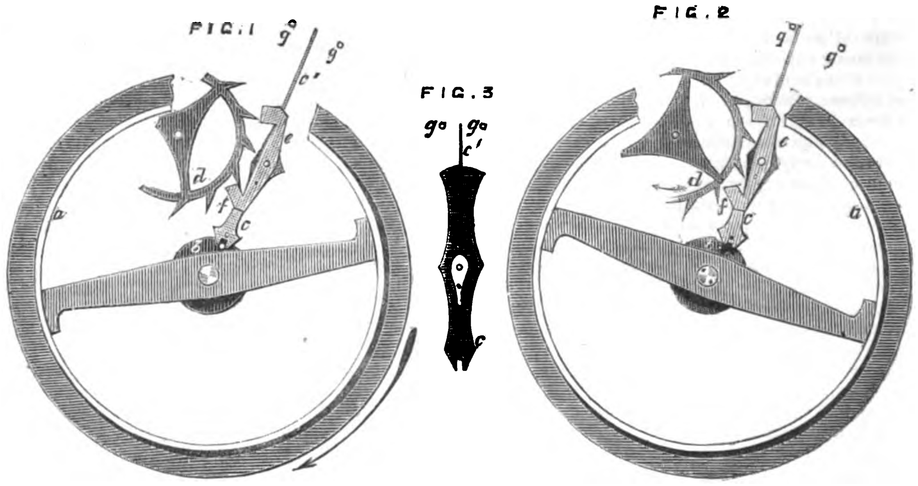
FIG. 3.



IMPROVED LEVER ESCAPEMENT.

BY MR. M. G. COLE.



of making the tail of the lever act as a spring, Mr. Cole sometimes fits a spring on to the pallet staff in addition to the ordinary lever, so that the spring shall act on the banking pins and yield to the second blow of the ruby pin.

Fig. 1 of our engraving shows a plan of the escapement of a watch with this invention applied to it. *a* is the balance wheel, with ruby pin *b*, which works in the fork of the lever *c* in the usual manner; *d* is the escape wheel, and *e* are the pallets carried by the pallet staff *f*, and secured to the lever *c*. The tail c^1 of this lever is formed quite thin so as to act as a spring, and works between the banking pins *g g*. If now the balance wheel, having received the impulse given by the action of a tooth of the escape wheel on one of the pallets communicated through the lever, should from any cause be moved so far round that the ruby pin *b* strikes against the outside of the fork of the lever *c*, as shown in fig. 2, the tail c^1 of this lever resting at the time against the one banking pin will, through its spring action and the shape given to the forked end of the lever, allow the ruby pin *b* to pass by, when the spring tail will immediately cause the lever to regain its correct position for the ruby pin to act upon it in the contrary direction. The tail c^1 is, however, made sufficiently stiff to limit the ordinary motion of the lever by coming in contact with the banking pins. Fig. 3 shows a plan of another modification of the lever *c* in which, in place of forming the spring tail c^1 on the lever itself, such spring is formed separate from the lever, and is secured to the pallet staff *f* and to the lever.

We are informed that the patent right of this

invention has been acquired by and belongs to Messrs. E. Dent and Co., of 61, Strand. The escapement has been applied to a number of watches, and is found to answer the object in view most satisfactorily.

INSTITUTION OF CIVIL ENGINEERS.

THE annual general meeting of the Institution of Civil Engineers was held on Tuesday, December 21, Mr. C. H. Gregory, President, in the chair. In reviewing the events of the past twelve months, completing the fifty-second year since the foundation of the Institution, the council stated that the proceedings had furnished corroborative evidence of the sound basis on which the society was established. Referring to the business at the ordinary general meetings, of which there were twenty-two during the past session, attention had been directed by the papers read, and by the discussions upon them, to the use of machinery in lieu of gunpowder for getting coal; to cylinder foundations for bridges and other similar structures; to the Midland line of the Mauritius railways, where exceptionally steep gradients and sharp curves were necessarily adopted; to some of the chief peculiarities of American locomotives and rolling stock; to works carried out in connection with the river Witham and estuary, for the drainage of the fens and the improvement of the navigation; to the past and present condition of the outfall of the river Humber, and of its peculiar feature, Spurn Point; to the New Ferry and the New Brighton piers and landing stages on the river Mersey; to the Low Water Basin at Birkenhead, and the extensive sluicing operations for maintaining the basin at its proper depth; to the lagoons and marshes on certain parts of the shores of the Mediterranean; to the mechanical details of construction of lighthouse apparatus and lanterns; to the Roman Rock lighthouse, Cape of Good Hope; to the standards of comparison for testing the illuminating power of coal gas; and lastly, to an able summary, by a foreign engineer, of the present state of knowledge as to the theory of the strength and resistance of materials of construction. The originality, labour, and ingenuity displayed in these communications had led to the award of Telford medals and Telford premiums of books to Messrs. Jules Gaudard, W. Shelford, T. N. Kirkham, J. Ellacott, and D. T. Ansted, F.R.S.; of a Watt medal and a Telford premium of books to Mr. Z. Colburn; of Telford premiums of books to Messrs. W. H. Wheeler, J. R. Mosse, I. Bell, J. Milroy, S. P. Bidder, jun., and C. J. Chubb, and of the Manby premium of books to Mr. D. M. Henderson. In addition to the ordinary general meetings, there were six supplemental meetings, for the reading and discussion of papers by the students. For the papers read at these meetings, Miller prizes had been awarded to the following students:—Messrs. E. Bazalgette, F. H. Mort, T. J. Ellis, T. R. Gainsford, C. H. G. Jenkinson, and G. H. Roberts. It was stated that during the past year upwards of 700 volumes and pamphlets had been added, either by presentation or by purchase, to the library, which now contained about 5,800 volumes, and 4,300 tracts, on every branch of civil engineering, and in many different languages.

During the last session 30 members and 82 associates had been elected; but as the deceases, resignations, and erasures from the register were double what they had been in any previous year, the actual increase in the gross total of the several classes composing the corporation was only 42, or 2·7 per cent. on the present number. There were on the books on November 30 148 students, as against 133 at the same date last year. If the students were included in the enumeration, as the graduates used formerly to be, it would be found that the gross number of all classes now on the list was more than double what it was twelve years ago—1739 as against 857. The actual numbers of the four classes—honorary members, members, associates, and students—were 16, 655, 920, and 148 respectively.

The following gentlemen were elected to fill the several offices on the council for the ensuing year:—Charles Blacker Vignoles, President; Joseph Cubitt, Thomas Elliott Harrison, Thomas Hawksley, and George Willoughby Hemans, Vice-Presidents; James Abernethy, William Henry Barlow, John Frederic Bateman, Joseph William Bazalgette, Nathaniel Beardmore, Frederick Joseph Bramwell, James Brunlees, John Murray, George Robert Stephenson, and Edward Woods, Members and Edward Middleton Barry and Lieutenant-Colonel Andrew Clarke, C.B., R.E., Associates.

PALLISER CONVERTED GUNS.

THE complete success which has attended the conversion of upwards of 400 cast-iron 8in. smooth-bores into Palliser rifled cannon for the Admiralty has lately attracted the attention of the War Office to the importance of converting the thousands of 68-pounder cast-iron guns which are mounted on our coast defences both at home and abroad. Out of several hundred guns which have now been proved, in no instance has the slightest symptom of weakness presented itself. These conversions are due to the reports and recommendations of General Lefroy and the members of the late Ordnance Committee, and the practical results reflect great credit upon their labours. The recent visit of Colonel Jervois, the Deputy-Director of Fortifications, to Halifax and Bermuda has been the means of further demonstrating the importance of the subject. It appears that at the latter place alone upwards of 300 smooth-bore guns are mounted in the works, and although complete in their carriages, traversing platforms, embrasures, sponges, rammers, &c., they are, in their present smooth-bore state, no better than wooden dummies for opposing a bombardment at long ranges with rifled guns. The Secretary of State for War has, as a preliminary measure, authorised the trial at Shoeburyness of two rifled guns, a 7in. and an 8in., converted from old 68-pounder guns. They are to be fired at the "Warrior" target from a distance of 1,000 yards. The experiment is awaited with great interest, since if the guns penetrate the target at such a range it is expected considerable orders for conversions will follow. An old cast-iron mortar has also been converted, by Mr. Cardwell's directions, into a 9in. rifled mortar, and will be tried at the same time as the guns. It weighs about 6 tons, and it is expected that it will throw its shell of 250lb., containing a bursting charge of 20lb. of powder, upwards of 7,000 yards.

THE SOCIETY OF ENGINEERS.

ON Friday evening last the annual dinner of the Society of Engineers took place at the Westminster Palace Hotel, at which above a hundred members and associates and their friends were present. The chair was occupied by Mr. F. W. Bryant, the president of the society, the two vice-chairs being taken respectively by Mr. William Adams, the president elect for the ensuing year, and Mr. Alfred Williams, the honorary secretary and treasurer of the society. The customary toasts of a loyal and patriotic character were duly given and honoured, after which the toast of the evening —"Success and Prosperity to the Society of Engineers"—was given by the president in an able and practical speech. The President reviewed the early days of the society, and showed how from small beginnings it had risen to a position of influence and importance. Beginning with 55 members in 1854, it now enrolled nearly 500, and speaking on behalf of the council, he promised that they would not relax their efforts to further its continued progress; at the same time he had every reliance on the general body of its members in backing up their endeavour to make the society as successful as possible. The object of the institution was the promotion of engineering science and practice; and he congratulated the society on having, during the past session, had some excellent contributions to their transactions, both with respect to the papers read and the discussions which had followed them. Those discussions had been the means of eliciting much valuable information of which they could not otherwise have become possessed. The members had also had the advantage of making several visits of inspection in the course of the year to a number of great works in and around the metropolis, of great importance to the engineering world, and of having been received on those occasions, by the gentlemen who had the conduct of the works, with the utmost kindness and courtesy. In those visits they were favoured not only with an inspection of the plans, but with the experience of the gentlemen who were engaged in carrying them out. It was worthy of record also that in most cases where these visits had been made, the works were being executed under the direction of members of the Society of Engineers. No better method could be devised for promoting the study of engineering than in making visits to works in progress; for, in so doing, the members not only saw the works, but had the opportunity of disseminating among each other the ideas which might be suggested to them by anything they chanced to see at the time. Then by observation and discussion on the spot a large amount of information was diffused alike amongst the oldest and the youngest members of the institution, and especially the latter, of whom there was a considerable number in the society. The President, in conclusion, coupled the toast with the name of Mr. Alfred Williams, whose health was cordially received.

Mr. Williams, in replying to the toast, gave a *resume* of the financial and general position of the society, together with a statement of the details of its working. He alluded to its success, and pointed out the causes which had led to it. He further indicated how the present satisfactory position of the society could be not only maintained, but improved upon. This was by the combined efforts of the members and associates in reading and discussing papers on engineering and scientific subjects. He concluded by thanking the president for proposing and the company for honouring the toast, assuring them of his continued support and hearty co-operation.

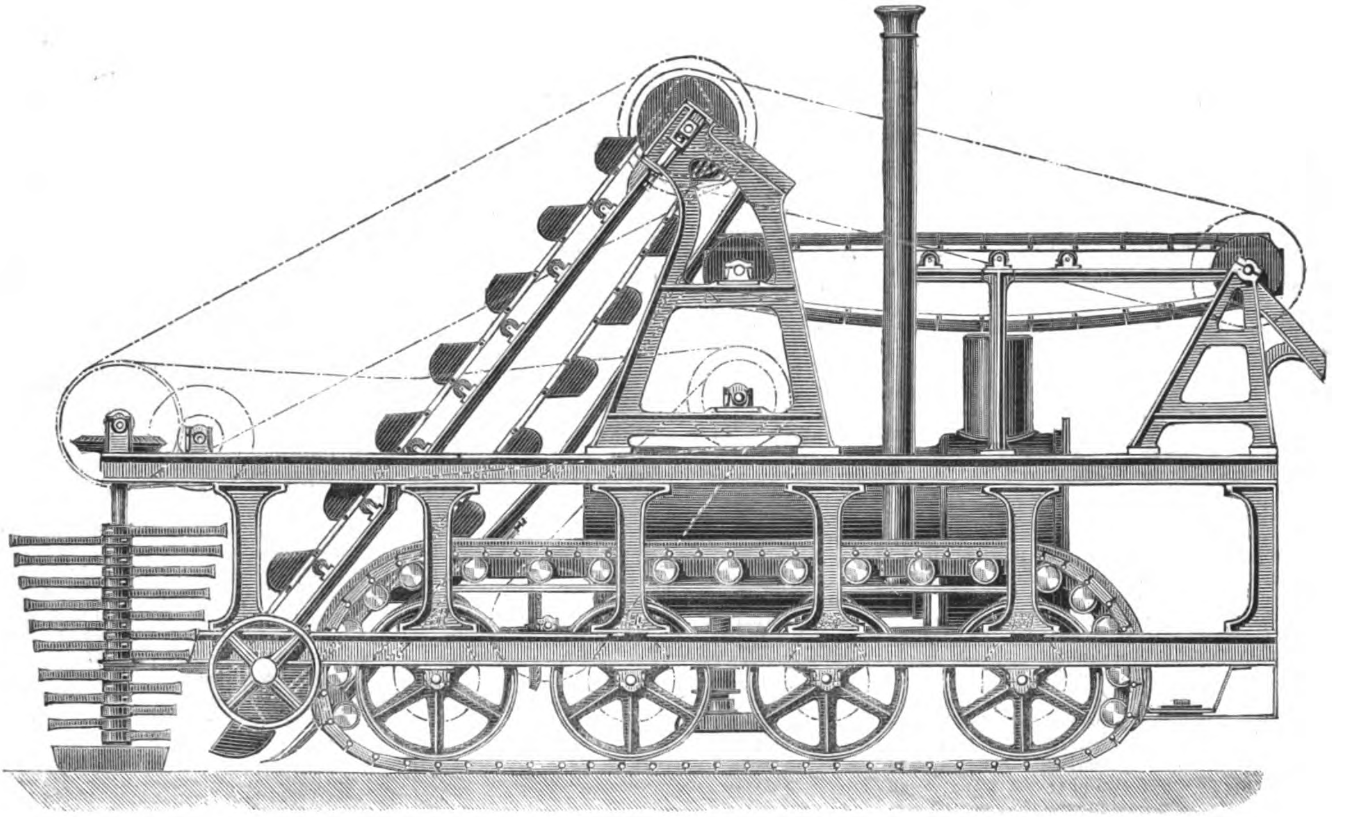
Mr. Olrick proposed the health of the chairman of the evening, Mr. F. W. Bryant (the President of the society), upon whose engineering services in connection with several of our great public works, including pre-eminently the new Blackfriars Bridge, he pronounced a high eulogium. He observed that if the bridge across the Channel was ever to be constructed he would advise the projectors in the first place to avail themselves of the science, experience, and skill of the chairman. Mr. Bryant duly responded to the toast. Several other toasts of a special and complimentary character were proposed and responded to, after which the company retired, a very pleasant evening having been passed. The proceedings were enlivened by music and song.

THE STONE AGE IN EGYPT.

A LETTER has been addressed by Messrs. Hamy and Lenormant to the Academie des Sciences to prove that Egypt has had its age of stone as well as Europe. Their letter is dated from Luxor, and they say to the secretary of the Academy:—"We beg you to communicate to the members a discovery we have just made in the course of a journey to Upper Egypt, undertaken under the auspices of the Khedive, which will not be devoid of interest to that learned body. The existence of an age of stone in Egypt has often been the subject of controversy. The facts we are about to relate will, we think, give some information that will exercise an influence on the opinions entertained hitherto on the question. On the elevated plateau which divides the celebrated valley of Biban-el-Molouk from the escarpments which overlook the Pharaonic edifices of Deir-el-Bahari, we have ascertained the presence of an enormous quantity of wrought flints, lying on the surface of the ground, to the extent of upwards of a hundred square yards. These wrought flints, which are of the well-known type designated arrow-heads, lance-heads, lanceolated axes, knives, scrapers, &c., evidently constitute the remains of an ancient manufactory, according to all probability pre-historic, and exactly resembling those known in France under the denomination of 'Factory of the Neolithic Period.' Messrs. Ballard, Quatrefages, Wurtz, Jamin, Broca, and Berthelot, with whom we had the good fortune to be travelling, were witnesses of the discovery, and authorise us to declare that they verify the origin of the specimens collected by us and their similitude to those found in Europe. The best of them we propose to deposit in the Museum of St. Germain, where they can be inspected by connoisseurs in antiquarian subjects."

A NEW EXCAVATING MACHINE.

BY M. VANDENVINNE.



EXCAVATING MACHINE.

We last week drew attention to a new digging and excavating machine, a working model of which the inventor, M. Florent J. Vandenvinne, of Belgium, is now exhibiting in the Ashburnham Grounds, Chelsea, and promised detail particulars, which we now append. The invention has been patented in England, and the machine, which we illustrate in side elevation herewith, is for the purposes of tilling or ploughing land to a great depth, and also for the execution of all kinds of open earthwork, such as cuttings for railways and canals.

On reference to our engraving it will be seen that the machine consists of a strong iron framework, on the back part of which is fixed a steam engine for giving a forward motion to the machine, and for driving its working parts. A pulley is keyed on the shaft of the steam engine, which drives a second pulley fixed on a horizontal shaft placed in the front of the machine. This shaft carries at each end a bevel pinion, each of which gears into two bevel wheels fixed on two vertical wrought-iron shafts. Around each shaft are keyed the picks or mattocks, arranged screwwise, and turning in opposite directions in such a manner that the picks of one of the shafts pass in spaces between the picks of the other shaft. These picks are curved so as to move the earth, which being struck by them is thrown back and falls into troughs placed to receive it. Curved sheets of iron are arranged so as to prevent the earth thus moved from falling at the sides. The troughs are fixed on an endless chain passing over two drums, one at the bottom and the other at the top of the machine. The shaft of the top drum is driven by a band passing over a pulley fixed on the horizontal shaft already mentioned. The troughs are thus constantly in motion, and carry up the earth to the top of the machine, and turn it over on an endless carrier, which passes over two drums, on the shaft of one of which is a pulley driven by a band from a pulley on the drum shaft of the trough chain. This endless carrier thus conveys the earth to the back of the machine, whence it may if required be carted away. Friction rollers are placed in suitable supports under the endless chain of the troughs, and also under the endless chain carrying the earth to the back of the machine, and at each side of the latter chain sheets of iron are fixed to prevent the earth from falling off, and two iron sheets, moved by a screw, are placed under the troughs on their descending side to prevent any earth falling into the machine.

The forward movement of the machine is effected by means of an articulated endless railway, on the lower part of which rest the wheels of the machine, the upper part being supported and moving on rollers fitted in a framing attached to the machine above and partially around the wheels. On a forward or backward movement being given to the machinery the endless railway lays itself continuously on the ground under the wheels. Arrangements are provided for guiding the machine laterally and also for working it at a dead level or at an upward or downward angle.

We inspected the working model of this machine at Chelsea on the 1st inst., through the introduction of Mr. John Jones, of 94, Stanley-street, Pimlico. Upon that occasion, the machine did its work satisfactorily, although it is only of small size, being of 3-horse power, and weighing 4 tons. It excavated the ground to a depth of 2ft. 3in. in a continuous line, breaking down the earth and carrying it to the rear in good style. It had a steady, although somewhat slow, rate of advance, but this would be increased in a more powerful machine. Mr. Jones informed us that he had seen one of the large-sized machines, weighing 12 tons, at work in Belgium, where it excavated the soil in excellent style. The invention promises to be of practical use in railway and canal works, as it removes the soil and throws it into waggons or upon the bank as required at a very small cost per cube yard.

BALLOT VOTING APPARATUS.

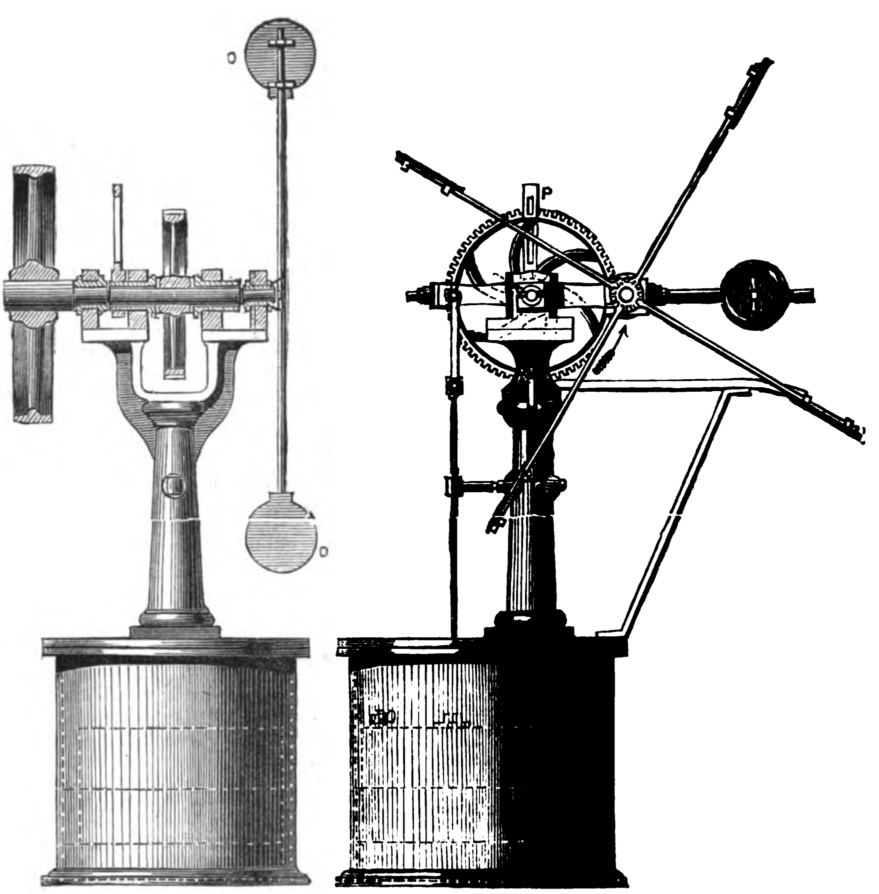
During the latter part of last week and a portion of the present there was on exhibition at the City Terminus Hotel, Cannon-street, a working model of a new ballot voting apparatus, which has been patented by Messrs. Cruttenden and Wells, of Maidstone, through Messrs. Robertson, Brooman, and Co., of 166, Fleet-street, London. A careful inspection of its working leads us to the conclusion that this invention affords a perfectly secure, simple, effectual, and economical means of taking votes by ballot. The voting is with balls corresponding in number to the persons to be elected, without reference to the number of candidates or voters; thus, if one is to be elected, only one ball will be used; if two, two balls; and so on. The apparatus consists of a small chamber, which in practice is made portable, measuring about 10ft. by 6ft., and having an entrance at one end and an exit at the other. The entrance and exit are revolving doors with four leaves, the passing through which registers the number of voters who have passed on the dial and counting apparatus attached to them. Under the flooring is a double-forked lever, actuated by a disc and stops under each door. The passing through the entrance door effectually locks it and renders it immovable both for entrance or exit, and at the same time the exit door is locked against entrance, and is only free to allow the voter to pass out, and his passage out liberates the entrance door for the next voter.

On the inside are a series of holes in compartments to receive the balls, each compartment of a different colour and number, with the names of the candidates. From these holes, corresponding to the size of the ball, are descending tubes or shoots, through which it immediately rolls and falls into a receptacle outside the apparatus in charge of the official, and is ready for the next voter; its passage through the tubes is registered on the dial and counting apparatus attached to each compartment by falling through a rotating drum wheel, which immediately locks itself after the ball has passed through it; and if another ball is by fraud or accident placed in the hole, it passes on down a waste tube, and is registered on a dial fixed for that purpose. The exit of the voter unlocks any drums that have been used, and leaves them all in their normal condition for the next voter. There is also a hole and a compartment for neutral votes. This drum does not lock itself, but like the drum for fraudulent balls registers all that pass, so that the voter can, if he chooses, not vote at all.

The method of using it is simple. The duly qualified voter presents himself to the official in charge of the balls, who gives to him one, two, or three, according to the number of persons to be elected; and these are to be the only balls used. The voter passes in, deposits them for whom he chooses, and leaves by the exit door. The balls immediately return to the official at the entrance; if they do not do so, it is known that the voter has detained them, and this must be punishable. If the voter should fraudulently put more similar balls in, they would merely be recorded on the waste drum, and he would stand convicted by their delivery to the official at the entrance. If any further security be required against wanton or malicious injury to the apparatus, a supplemental lever is attached to the mechanism under the floor,

A NEW REGULATOR.

BY HERR K. REIGERS.



which, on the exit of the voter, reveals the whole system—except the indicators, which are locked,—to the public or officials, and which closes again on the entrance of the next voter, who sees nothing but the holes for the ball in the coloured compartments of the candidates, the dials, tubes, and drums being securely locked and protected from his sight. There are also provided, in the side opposite to the voting compartment, sliding or folding doors, securely locked, for the officials, candidates, or representatives to enter and set the dials at zero before the opening of the poll, and to ascertain the result at the close without disturbing the revolving doors and indicators.

The mechanism is extremely simple, there being no springs which might break or fail, but simply lever movements, the motive power for which is unfailing, being entirely supplied by the passage of the voter into and out of the apparatus, and the passage of the ball down the tubes. The advantages of this apparatus will be at once apparent to those who have followed our description, and are such as commend the invention as embodying the most perfect system of voting extant.

THE REIGERS-KRAFT REGULATOR.

IN the annexed engraving we show two views of the Reigers-Kraft regulator, which is highly spoken of upon the Continent. Professor D. Grotteman, of the Polytechnic, at Delft, amongst others, has stated it to be a very efficient instrument. The following are the principles upon which it is based:—If by means of a pair of wheels, a gyratory motion is imparted to an axle, which has to overcome a certain resistance, the power employed will manifest itself in two ways. It will strive, firstly, to turn the axle; and, secondly, to remove the same in its—the power's—direction. This necessitated a foundation for the apparatus to stand upon, the pressure of which will be greater or less than the power acting upon it. The influence of the latter will manifest itself by the resisting or yielding of the former; but if the pressure be so regulated as to be neither greater nor less, then the apparatus will be held in suspension as long as the power remains the same. A change in the latter will bring about a rising or falling of the foundation. The resistance which the axle has to overcome depends upon the increased or decreased endeavour to remove it, and, moreover, upon the pressure and the power which the axle has to transmit. These principles are jointly used in the instrument before us. The axis N on a movable foundation K would be raised by an increase of power (or the increased resistance of the vane O), and lowered with its diminution; the equilibrium of both effects of the power would hold K in suspension. The pressure of K is affected by the speed of the motion, since the resistance of the same is in proportion to the square of the velocity of its circumference. The suspended weight K can only be retained in its position by the exact normal velocity of the motion; the angle which the lever I may form with a horizontal line will not influence that position as long as both effects of the power upon the axle remain in equilibrium. This, however, can only be the case when the speed of the engine is the normal one, and hence the Kraft regulator will not permit a change of that speed, since the equilibrium of the effects would thereby be interrupted. The gap of the throttle valve may be changed without disturbing that equilibrium.

THE ROYAL POLYTECHNIC INSTITUTION.

PREPARATIONS for the forthcoming season of Christmas, although at the present time universal in the social world, are hardly looked for in the domains of science. Nevertheless, they are to be found there, and nowhere are they more actively carried on than in that home of science—pure and popularised—the Royal Polytechnic Institution. The directors of this favourite place of entertainment and instruction, with Professor Pepper at their head, have prepared a programme in which there is nothing wanting to please all ages, and to edify while it amuses. From a private view which was accorded us last evening, we are enabled to indicate to the public what a marvellous shilling's worth awaits them on their Christmas holiday visit to the old Polytechnic. We of course take it for granted that everyone will visit this establishment. If they do not, theirs be the fault, and not ours. But to proceed, Professor Pepper has prepared a new lecture, entitled "A Shocking Jar," in which the great lightning inductorium, having been thoroughly cleaned and renovated, is made to charge the largest Leyden battery in the world and the largest Gassiott's cascade apparatus is introduced. Immense lengths of wire are also deflagrated, and other startling experiments are shown. A mechanical novelty of great ingenuity has been introduced. It is termed the "Neurocrypt," or, the Woman of Hidden Nerves. It is an automaton of entirely new construction, by Mr. J. S. Cavill, and exhibits by a beautiful figure, the size of life, an almost indefinite series of graceful evolutions and attitudes, the most surprising imitation of spontaneous action we have ever seen produced.

The ghost illusion is as interesting as ever, and will not lose in popularity by its new garb—"The Mysteries of Udolpho." Here Professor Pepper causes innumerable spirits to appear and disappear. Mr. Pichler produces the startling novelty of three spirits emanating from one, and mysteriously returning to their "shadowy homes." The heroine of the romance dresses for a soirée; the spectres of her ancestors watching her movements. The celebrated baths of Homburg are shown. Live black beetles crawl over the dungeon walls, and many other startling appearances are produced. Christmas and Christmas customs are happily introduced in a novel manner by Mr. W. Wardroper, the pictures illustrating the story being highly appropriate; Christmas carols being introduced with excellent effect. Mr. J. L. King gives an instructive lecture on the Tentoonstelling, or international exhibition of Amsterdam, whilst the mysterious hand still pursues its inexorable caligraphic task of writing down all the visitors' names. But we must stop; we have not time to tell of all we saw at the Polytechnic last night, as we are going to press. We have, however, indicated some of the novelties, and leave the rest as a pleasant surprise to our friends the public.

PAPER BLUE.

AN invention which promises well for laundry establishments has been patented by Mr H. B. Binks, and is being practically carried out by Messrs. Forbes, Born, and Co., of No. 2, South-place, Finsbury. It consists in substituting blue coated paper for the ordinary blue bag, and is more economical as well as more convenient. In manufacturing this article the inventor takes indigo of the best quality, and after it is finely ground and sifted he dissolves it in acid in the proportion of 3lb. of acid to 1lb. of indigo, and allows the mixture to stand for three days. After this there is added to every pound of indigo 20lb. of water and 5lb. of cow hair, the whole being boiled for three hours, or until it becomes of a greenish hue. This is then allowed to remain twenty-four hours standing. The hair is then taken out and washed in clear cold water until a beautiful blue colour appears. The hair is then put in 10 gallons of water and boiled, and, whilst boiling, potash is added in the proportion of 10lb. of potash to 1lb. of indigo, thus rendering the indigo solution free from acid. The whole is then strained and evaporated to half its bulk, and allowed to remain thirty-six hours standing. Two fluids are now formed; the upper thin portion, when mixed with size, can be used as a blue writing ink; the lower portion, containing the real indigo-carmine, is then put in a wide but shallow vessel, and some glycerine added in the proportion of ¼oz. of glycerine to 1lb. of indigo. Unsized paper is then dipped in the solution, and in a few minutes the paper takes up the colouring matter. The paper is now dried and pressed, and is then ready for use as a colouring and bleaching agent for use in the laundry, and for manufacturing purposes. Professor Attfield, F.C.S., has had this paper blue submitted to him, and he writes that he has fully examined and tested it, and is of opinion that it contains nothing likely to injure the fibre of linen goods in any way whatever, and that it possesses many advantages over the older forms of blueing.

AN article of colonial production which has for years past, from time to time, attracted public notice, seems now to have some chance of assuming, ere very long, an important place in the exports of Mauritius. This is aloe fibre, which is now being extracted for exportation by several persons; and in Bourbon, where sugar planting has ever been less successful than Mauritius, a still larger amount of attention has been bestowed on this fibre; and machines have been erected in several places, capable of beating out 1,000lb. of it per diem. The aloe (that known as the Yucca) grows wild in immense numbers on these islands; and, like all species of aloes, it is very hardy, being little affected by dry seasons. The fibre is worth £25 to £30 per ton in Europe, and it is believed that it will gradually become an article of considerable importance in the colony.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular December 23.)

Since our last report, there is nothing special to note in the chemical market. As previously stated, the greater number of the large manufacturers are well sold forward; but there are yet a few considerable makers who prefer to sell for present consumption, with the hope of improving values next year, but, with the raw material receding in price, there are no present signs of any advance, although a rise in alkalies of 5 is not at all improbable. There has not been much activity displayed in minerals. Oolitic ironstone is commanding more attention in Staffordshire, and some of the Welsh ironmasters are also alive to its importance. In metals a large business has been done both in Scotch and Cleveland pig iron during the week, and a considerable advance has taken place in the prices of each. In manufactured iron there is little doing. Ingot copper is inactive. Manufactured is in pretty good demand for export, and smelters are firm at their quotations. An official reduction of £3 per ton has been declared in English tin. Lead firm at present rates. Spelter is still quiet, and prices remain about the same as last week. Soda: caustic soda finds unwilling purchasers beyond £13 for 60; for soda ash there is more inquiry, at £7 for 48; soda crystals, rather firm, at £4. Salt cake maintains its value; bicarbonate is still inactive, at £9 to £9 5s. Nitrate of soda obtains from £15 to £15 10s. per ton. Potash: muriate is still a short supply, with prices ruling firm at £7 7s. 6d. to £7 12s. Saltpetre: Bengal, 22s. to 23s. 6d.; English refined, 26s. 6d. Alum: a considerable trade has been done, at prices not exceeding £6 5s. for lump, £7 in export barrels, and ground at £7; in London, 10s. per ton above these prices. Ammonia: sulphate is in steady demand, at late rates of £15 10s. to £17; muriate in request at £22 to £28. Copperas: for green and rusty there is less demand; dry remains firm, at 50s.; chloride of iron, 50s. Pyrites: a rather firmer market; calcined in tolerable request at 44s., with 43s. 6d. asked. Lime: in phosphate, there is less doing, at 52s. 6d. on 65; bleaching powder is firm, at £8 for 35; disinfectants sell readily at £5 5s. per ton for the best quality. Manganese shows a falling market, and is without animation. Iron ore: Hematite sells at 15s. to 18s.; oolitic firm, and in great demand at 6s. 6d. to 8s., in Staffordshire. Guano: for best Peruvian £13 10s. is asked.

Metals.—Iron: Scotch pig iron steady at 58s. 6d. to 58s. 9d. Cleveland, firm, at 49s. for No. 4 forge, to 53s. 6d. for No. 1. Welsh bars, £6 5s. to £6 10s.; Staffordshire bars, £7 10s. to £8 10s.; Gas tubes, 60 to 67½ off list; Boiler tubes, 40 to 42½. Copper: quiet; English tough, £71 to £73; Chili slab, £66 5s. to £67 10s. Tin: reduced; English ingots, £117; Straits from £110 to £111. Lead: firm; P. G. best English soft pig lead, £19. Spelter: dull; English, £20 to £20 10s.; Silesian, special brands, £19 10s. to £19 12s. 6d.; hard spelter, for export, £16 10s.

Correspondence.

HYDROSTATIC STEERING APPARATUS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In a recent number of your valuable journal I read a letter signed by Rear-Admiral Inglefield on the subject of his hydrostatic steering apparatus, which was at that time being fitted on board H.M.S. "Achilles." On trial it was reported to have been successful as regarded its action, but was found to be rather slow, especially in giving a "small helm." I am deeply interested in the success of this most valuable invention, as I believe it to be the simplest and most easily applied mechanical arrangement yet devised for steering merchant ships as well as men of war. I shall be glad to learn how the final trial which recently took place off Portland succeeded; also the actual time occupied in moving the tiller through a small and the extreme number of degrees from amidships. I should not have troubled you in this matter but that, as you are well aware, we outsiders have no means of access to the official reports, and we must therefore cast about us as best we may for valid information. I am told that to overcome the difficulty of obtaining a "small helm" in a short time, Messrs. Kittoe and Brotherhood, the engineers who made and fitted the machinery for the Government, proposed to enlarge some part of the apparatus. Can the Admiral or these gentlemen give me, through your columns, a description of these alterations and the results of the final trial. In so doing they will confer a great favour on,—Sir, yours, &c.,

A Seafaring Man of the Modern School.

London, December 20.

AN INVENTIVE PEOPLE.

Sir,—Some of your readers may not have realised the significance of a fact in the paragraph under the above caption in your number of November 19—"Over 40,000 specifications lodged in a year, and this in the States alone." A glance at the current list of English patents in your last impression shows that our own applications during the same period will not aggregate 4,000! As Englishmen, whose very existence depends upon manufactures, is it not ominous of our decadence that we can calmly witness the spectacle of a country, designed by nature mainly for agriculture, showing a patent roll ten times as large? Should it be tolerated that, whilst the cost to an American of a seventeen years' patent, examined by a board, is £18, an Englishman must pay for a fourteen years' uncertified patent considerably over £180?—I am, Sir, yours, &c., Frank Spence.

Manchester, December 20.

[The paragraph in question is quoted from the "Gentleman's Magazine," and it commences by referring to 14,000 patents, so that 40,000 would seem to be a misprint. Fourteen thousand is about the average number of United States patents for the last two or three years, but this shows a great disproportion when compared with our own. During the present year the total number has nearly reached 20,000. The cause is doubtless in some degree attributable to the heavy fees.—Ed. M. M.]

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

Tues.—Royal Institution.—Professor Tyndall on "Light" (juvenile lectures), at 3 p.m.

Thurs.—Royal Institution.—Professor Tyndall on "Light" (juvenile lectures), at 3 p.m.

Sat.—Royal Institution.—Professor Tyndall on "Light" (juvenile lectures), at 3 p.m.

Naval, Military, and Gunnery Items.

Captain Jones, of the ship "Victoria-Nyanza," arrived at Liverpool from San Francisco, reports having passed off Cape Horn an enormous iceberg 350ft. high.

The Abyssinian medal has been issued to officers and men proceeding on foreign service; but the one for the New Zealand war, which was virtually over before the attack on the late King Theodore was contemplated, still "hangs fire."

Indications accumulate that the success of the Suez Canal will rapidly bring about a solution of the question of the practicability of a ship canal to unite the Atlantic and Pacific. The Nicaragua route seems at present to attract the most attention.

A telegram has been received in Liverpool which states, on the authority of M. Lavalley, that the minimum depth of water over the Serapeum-rock is 18ft. 5in. A rumour that the Suez Canal was to be closed until April for dredging purposes is officially contradicted.

The Government (the "Broad Arrow" learns) are about spending £25,000 upon improvements at the Royal Military Academy, Woolwich. The improvements contemplated consist of separate rooms or studies for the cadets, and a chapel for their spiritual behoof. It is said that these improvements were suggested by the report of the Royal Commission on Military Education.

An extensive order has been received at the Royal Laboratory, Royal Arsenal, Woolwich, for the manufacture of a quantity of shells for the muzzle-loading rifled guns, which has enabled the department to re-engage the 50 hands in the shell foundry who were discharged last week. This order will, we understand, keep the hands now engaged at the foundry fully employed up to March 31 next.

Most of the gunpowder hitherto stored at Upnor magazines, to the danger of the Government establishments at Chatham, and of a very large population, having now been removed to the magazines at Purfleet, the extensive buildings at Upnor will be made useful for the warehousing of barrack stores, blankets, rugs, &c., a considerable quantity having been already deposited there, removed from the military department at Sheerness.

The official returns for the year 1868 show that in that year there were employed in British ships registered in the United Kingdom 177,239 British seamen (including all capacities expect masters) and 20,263 foreign seamen; the number of apprentices bound and registered in British ships was 4,975. In 1867 the number of foreign seamen was 21,817; in 1865, 20,280. The number of apprentices was 5,638 in 1865, 5,454 in 1866, and 5,444 in 1867.

Four complete machines for the manufacture of Boxer cartridges for breech-loading rifles have been prepared and packed in the Royal Arsenal, Woolwich, for the use of the Ordnance Departments at Bombay, Madras, and Calcutta. The packages are being shipped for conveyance to their destination, and on their arrival the machinery will be put together, and cartridges made in India in sufficient quantities to meet the regular demand, thus saving the expense of the cost of their carriage from England.

Miscellanea.

It is announced that a treaty has been concluded with England, reducing the rate of letter postage after New Year's day to six cents (three pence) per half ounce. Newspaper rates are to remain unchanged.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending December 18, was 2,220. Total number since the opening of the Museum, free daily (May 12, 1858), 1,688,961.

The annual meeting of members of the London Association of Foremen Engineers will take place at the City Terminus Hotel, Cannon-street, on Saturday, January 1, at 8 p.m., when the accounts of the society will be audited, and officers for the ensuing year elected.

A magnificent display of spots is now sweeping across the sun's disc, and which in clear intervals are well defined even in a very moderate telescope. In the northern hemisphere are two groups, extending each over a space of between 140,000 and 150,000 miles, and full of curious and interesting detail.

There is said to be a papier-mache church actually existing near Bergen, Germany, which can contain nearly 1,000 persons. It is circular within, octagonal without. The relievos outside, and statues within; the roof, the ceiling, the Corinthian capitals, are all papier-mache, veneered waterproof by a saturation in vitriol, lime water, whey, or the whites of eggs.

The collection of prints produced by various processes, used to illustrate Mr. Davenport's paper, on prints and their production, read on the 8th inst. before the Society of Arts, will be open for the inspection of members and their friends at the Society's House, Adelphi, between the hours of 10 and 4 o'clock, up to Saturday, January 8, 1870, inclusive.

The number of visitors to the South Kensington Museum during the week ending December 18, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 8,895; Meyrick and other galleries, 1,148; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,677; Meyrick and other galleries, 78; total, 11,798. Average of corresponding week in former years, 8,295. Total from opening of Museum 9,005,605.

"Abyssinian gold" is the name given to a new metallic combination which has been effected by Messrs. L. and A. Pyke, of 17, Thavies' Inn, Holborn. This new metal very closely resembles, both in weight and appearance, certain qualities of gold. It is, of course, only sold as an imitation, although a most successful one, of the real article. When made up into articles of jewellery, it is coloured, and when this colouring wears off, it developes the material, which for its price is the best imitation gold we have seen. When this material becomes tarnished or dirty—and the best gold is liable to this—soap and water and a brush will restore to it a good appearance. We have seen some excellent examples of jewellery in this new metal, and we shall no doubt astonish our readers when we state that their total cost is only about one-fourth that of the labour cost of the best gold. How the inventors can supply their goods at the merely nominal price they do is a mystery to us.

MESSRS. LETTS and SONS, of the Royal Exchange, whose diaries we noticed last week, have published a large sheet almanack for 1870, which contains a variety of information, and which, for usefulness and low cost, is in keeping with the remainder of their productions. We may also draw attention to their sectional paper, which is ruled in faint lines and will be found very useful in the engineer's or architect's office for plotting upon. Of universal use also are Messrs. Letts' gummed labels, which are ready to be severed from a book and stuck—like postage stamps—on anything requiring them.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—1668, 1670, 1701

BUILDINGS AND BUILDING MATERIALS—1689, 1690, 1691

CHEMISTRY AND PHOTOGRAPHY—None

CULTIVATION OF THE SOIL, including agricultural implements and machines—1654

ELECTRICAL APPARATUS—None

FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—1657, 1664, 1673, 1686, 1687, 1707

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments &c.—1676, 1680, 1681, 1693, 1696

GENERAL MACHINERY—1660, 1672, 1677, 1682, 1699

LIGHTING, HEATING, AND VENTILATING—1675, 1683, 1684, 1694, 1711

METALS, including apparatus for their manufacture—1706

MISCELLANEOUS.—1653, 1655, 1658, 1661, 1665, 1666, 1671, 1678, 1688, 1697, 1700, 1702, 1710, 1712

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1651, 1662, 1663 1667, 1669, 1695, 1703, 1704, 1708

SHIPS AND BOATS, including their fittings—1652, 1459, 1679, 1705, 1709

STEAM ENGINES—1656, 1685, 1692

WARFARE—None

1651 F. BROWN, Luton. *Velocipedes.* Dated May 28, 1869.

The inventor transmits motion from the steerage handle to the brake lever by forming the stem or axis of the steerage handle with a short arm standing out from it, and this arm he connects by a short link to a fork, the prongs of which pass down on opposite sides of the vertical axis upon which the fork carrying the axle of the front wheel of the bicycle is carried.—Patent abandoned

1652 A. T. FAIRGRIEVE, Sunderland. *Coating ships bottoms.* Dated May 28, 1869.

To make 50lb. of the improved composition employed, the inventor takes 36lb. of common resin, and melts it in a pot under a slow fire. As soon as the resin is melted he adds 10lb. of the best Russian tallow, and 10lb. of raw linseed oil; as soon as these ingredients are properly melted together and combined, he mixes together in a separate vessel or pot 4lb. of quicklime, 8lb. of black lead, and 6lb. of flowers of sulphur, all in powder. These are to be well mixed together dry and without heat.—Patent abandoned.

1653 J. FRASER, Liverpool, and L. and R. SIMON, Nottingham. *Cutting pasteboard.* Dated May 28, 1869.

The circular knives are placed between discs of wood for other suitable material) and of various thicknesses, the discs when placed together with the circular knives between them forming the two cylinders, which are fixed in a suitable frame, and actuated or turned by any suitable power.—Patent completed.

1654 J. L. HANCOCK, Sutton Coldfield. *Hay making.* Dated May 29, 1869.

This consists in constructing the apparatus of a plate formed with a point at its front end, and its back end with a series of prongs or bars which are bent upwards and curved in such a manner that they form a surface similar to a mould board of a plough.—Patent abandoned.

1655 J. L. HANCOCK, Sutton Coldfield. *Clipping horses.* Dated May 29, 1869.

This consists in making one of the blades of scissors or shears used for clipping and trimming horses and other animals and for shearing teeth with a series of teeth formed during its manufacture or after it is made, and before being tempered and finished or after reducing its temper.—Patent abandoned.

1656 A. HEMINGWAY, Manchester. *Slide valves.* Dated May 29, 1869.

The inventor forms the back of the valve open, and places in the interior or plate, which rests on one or more rockers linked or toothed to the plate, which plate is kept tight by a shelf of indiarubber or a metallic packing. When there is only one rocker it works on metal in the middle of the exhaust port or passage, and as the valve is moved to and fro, the rocker rocks on the metal and thus the friction is reduced to a very great extent, there being only sufficient valve surface to keep the valve tight to its facing, and when there are two rockers they work on metal at the ends of the exhaust port or passage, and support the plate pressed by the steam or water.—Patent completed.

1657 E. J. HUGHES, Manchester. *Printing cloth.* (A communication.) Dated May 29, 1869.

The inventor prepares the cloth or yarn with acetate of lime or with hyposulphite of calcium, then prints the colours with lactarine dissolved in ammonia or other known processes, and steam as usual.—Patent abandoned.

1658 W. H. TURNER, Blackburn. *Lessening smoke.* Dated May 29, 1869.

When adapting these improvements to the furnace or to each furnace of a steam boiler, the inventor fits a dead plate to the front of the furnace immediately inside the doors thereof, the dead plate being formed with an interior space for the passage of air, and the space being preferably divided by means of horizontal or nearly horizontal or vertical or nearly vertical partitions, or by means of partitions so arranged as to cause the air when passing through the space to take a more or less circuitous course, in order that the temperature of the air may be raised.—Patent abandoned.

1659 J. HUMPHREY, Aberdeen. *Iron keelsons.* Dated May 29, 1869.

The keelson is constructed of T angle iron, and the foundation plate thereof is fitted on planking formed by preference of East India teak. In order to secure the keelson in its position, bolts of yellow metal cast with round heads thereto are driven through the keel and flooring and passed through holes formed for the admission thereof in the keelson.—Patent abandoned.

1660 J. STURGEON, Bolton-le-Moors. *Getting coal.* Dated May 29, 1869.

This relates, first, to certain improved arrangements of valves and valve mechanism in engines, for condensing or compressing atmospheric air to be used as a motive power in connection with the getting of coal and other minerals. Instead of the clack valves employed in such engines, the inventor applies to the induction passages, valves which are actuated by suitable self-acting mechanism directly from the engine itself, or by springs or weights the action of which is controlled and regulated by the engine through suitable mechanism, while the eduction passages are opened and closed in the ordinary way, namely by valves so arranged as to open by means of the air pressure within the cylinder, and to close by the pressure of the air in the receiver or vessel into which it is forced.—Patent completed.

1661 J. M. MUTERSE and H. G. DE VALORY, Guerande, France. *Anti-flame powder.* Dated May 29, 1869.

The component parts of this compound substance are: —Magnesium, aluminous silicates, from salt marshes in a very fine powder, and dried at a heat of 212deg. Fah., 700 parts by weight; chloride of magnesium, in crystals, 200 parts by weight; sulphate of soda, 50 parts by weight; chloride of lime, 50 parts by weight; tartaric acid, 1 part. Total, 1,001 parts by weight.—Patent abandoned.

1662 A. A. SAX, Paris. *Helicoidal railway.* Dated May 29, 1869,

This consists in establishing railways by means of a suitable number of helices connected endwise so as to form one continuous line or way; each helix is formed of one or more bars, or very stout wires of iron, or other suitable metal, and in the interior of the helix or helices are situated one or more cars, which may be caused to move forward or backward by imparting to the helix a rapid revolving motion round its axial line, for which reason the inventor calls this mode of propelling helicoidal propulsion. The periphery of the wheels of the cars is provided with a groove by means of which the wheels are allowed to roll along the wire or bar of the helix, the weight of the cars keeping these latter in the vertical position.—Patent abandoned.

1663 E. DAVIS, Great Mitchell-street. *Velocipedes.* Dated May 29, 1869.

The cranks of the crank axis or the crank pins by which a velocipede is propelled are connected by means of connecting rods with volute, curved, or other springs, and the inventor provides these springs with treadles or handles, or both handles and treadles, by which the velocipede can be propelled with great facility, the springs yielding to some extent and lessening the shock when an obstacle is encountered.—Patent abandoned.

1664 J. SMITH, Loth, Belgium. *Holding bobbins.* Dated May 29, 1689.

This consists in fitting two or more springs in recesses in the stem of the tube or spindle employed in spinning and cap frames; these springs for a portion of the circumference of the tube act upon the inside of the bobbin and hold it thereon by the centrifugal action of the tube or spindle in revolving. In some cases the springs may be fitted to a washer or other appliance on the lifter of common spinning frames in order to regulate the drag of the thread passing on to the bobbin.—Patent completed.

1665 J. F. NICHOLLS, Bristol. *Converting dining into billiard tables.* Dated May 29, 1869.

The inventor affixes by means of clamps around the top of the table ledges of the proper shape and size carrying cushions of indiarubber. The cushions he forms of indiarubber tubing laid in a groove along the front of the ledges and made to adhere thereto, such tubes being allowed to project about three-fourths of their diameter from the grooves; the ledges may be of wood, enamelled slate, marble, or iron. The adjacent ends of the table the inventor connects together by metal segments, the ends of which are bent down to fit into socketed holes in the ends of the ledges, and on these segments are threaded the pockets for the balls.—Patent completed.

1666 J. J. R. HUMES, Deptford. *Brick moulds.* (A communication.) Dated May 29, 1869.

The plungers or pistons are faced with porous wood, the wood being cut across the pores or grain and arranged so that the pores are presented endwise to the brick space of the mould.—Patent abandoned.

1667 J. COCKSHOOT, jun., and H. WEATHERILL, Manchester. *Axles.* Dated May 31, 1869.

This consists in recessing the split washer in order that the back collar of the axle box when received within the recess of the solid flange will allow the split washer and such solid flange to lay in close proximity, giving greater rigidity when bolted up; second, the improvements relate more particularly to the class of axle known in the trade as the "Collinge axle" and consist in enlarging the ordinary recessed collar thereof so as to make it deeper and larger in diameter, so that the inner surface can be tapped with a screw thread for the purpose of receiving a split nut having a number of elongated holes around its circumference.—Patent completed.

1668 P. KIRK, Workington. *Puddling furnaces.* Dated May 31, 1869.

The inventor forms the fire-grate in two portions, namely, an upper and a lower portion. The upper portion is formed by preference of a circular, hexagonal, or polygonal shape on plan, with the sides perforated or slotted and sloping downwards and towards the centre, and is made of a suitable material, as for example of cast iron which material the inventor has formed to be peculiarly suitable.—Patent completed.

1669 H. T. BRAITHWAITE, Cardington-street. *Bicycles.* Dated May 31, 1169.

This consists in the application of a forked rod or slide or system of rods or slides furnished with props, rests, or rollers to either or both wheels of or between the wheels of two-wheeled velocipedes or bicycle worked from above, below, or sideways through bearings parallel to or vertically projecting upon any supposed plane parallel to or meeting the planes of the wheels and forming part of or being attached to the ends, sides, or any other part or parts of the main frame.—Patent abandoned.

1670 J. HANWORTH and H. HORSFALL, Todmorden. *Furnaces.* Dated May 31, 1869.

The inventors make use of a set of stationary tubular gratebars connected to a chamber at the front of the boiler, and to a water pocket near the bridge, which is in communication with the lower part of the boiler, to ensure a free circulation of water through the tubular gratebars; they also employ in combination therewith one or more sets of solid gratebars placed in front of the tubular gratebars, and a sliding plate, to both or all of which to-and-fro motions are given. The sliding plate works under the hopper and carries the coal from the hopper to the sets of solid gratebars, which in like manner deliver it to the tubular gratebars.—Patent completed.

1671 R. S. BARTLETT, Redditch. *Needle cases.* (A communication.) Dated May 31, 1869.

The external part of the needle case or holder is made by preference of an ornamental cylindrical figure. Within the cylindrical part is a series of six or other number of tubular cases of a length greater than that of the longest needles to be stored in the case or holder.—Patent abandoned.

1672 B. LITTLER, Cannock. *Circular saw guard.* Dated May 31, 1869.

This consists in applying to circular saws a guard constructed and arranged in such a manner that the ascending side of the saw is so protected as to prevent anything being brought accidentally in contact with it.—Patent completed.

1673 J. BULLOUGH, Accrington, and C. CATLOW, Burnley. *Looms.* Dated May 31, 1869.

In the space between the healds and the reed an additional heald (which the inventors term "float heald") is suspended from the heald roller bearings, and the lower end is attached by a spiral or blade spring to the cross rail or other convenient part of the loom, the float heald also being connected to the sley beam by a cord or chain. Between the float heald and the reed they place a corse or float reed, to which is attached and working in connection therewith a finger resting on a catch having one or more notches therein. This finger acts on a projection on a stem of the weft fork, when a float occurs and stops the loom.—Patent abandoned.

1675 G. PRESTON and J. PRESTIGE, Deptford. *Lamps.* Dated May 31, 1869.

This consists in making the lens of uncoloured glass, fluted or not, and in fitting the interior of the lamp with thin coloured glasses in a frame which may be movable or not.—Patent abandoned.

1676 R. MATHERS, Leeds. *Mattresses.* Dated May 31, 1869.

The inventor constructs a support for the mattress by placing longitudinally upon the bedstead or other similar frame a series of laths resting at their ends upon helical springs. He supports the middle of the above laths as follows:—He places at suitable distances apart two cross bars, so that they shall carry a series of flat springs (metallic or otherwise) having a corresponding series of small wooden blocks, which connect the springs with the laths and afford them elastic support.—Patent completed.

1677 J. DOCKRAY, Leeds. *Carding engines.* Dated May 31, 1869.

The inventor communicates to the main cylinder a slow lateral reciprocating motion, by which it is made to act against each of the rollers by and upon which the material acts and is acted upon. The inventor effects the lateral motion above named by placing upon the first feeder shaft or other shaft moving at a similarly slow rate a cam which communicates the reciprocating motion required through a lever or levers adjustable so that the amount of oscillation communicated to the main cylinder and feeder respectively may accord with the work to be performed.—Patent completed.

1678 W. E. NEWTON, Chancery-lane. *Locking corks in bottles.* (A communication.) Dated May 31, 1869.

The invention comprises a locking cap, constructed upon the principle of what is known as a letter or combination lock, and is composed in part of a series of internally flanged and notched movable rings, operating in combination with a series of fixed lugs upon the neck of the vessel or upon a collar attached thereto, so that by turning the rings after the cap has been placed upon the neck (over the stopper) the relative position of the notches with that of the fixed lugs will be so changed as to effect the locking of the cap upon the neck and thereby prevent its removal until the relative position of the parts has been again established, when it may be lifted off or displaced so as to allow of the extraction of the cork or stopper.—Patent completed.

1679 D. EVANS, Hackney. *Ships.* Dated May 31, 1869.

In constructing ships the inventor employs plates of iron or steel, flanged at the edges on one or both sides, and he welds the flanges of the plates together. Or he

causes the plates to meet with a butt or a lap joint. He covers the joint with a flangeless plate or wide bar either at the front or back or on both sides, and he welds the whole together.—Patent abandoned.

1680 J. KING, Norwich. *Cinder sifter.* Dated May 31, 1869.

This consists in forming it somewhat like an ordinary dust pan, such as is used by housemaids, with the difference that, instead of making the bottom thereof solid, the inventor proposes to form it as a sieve, beneath which he fits a sliding drawer to catch the dust, or he forms a chamber beneath with a small door at one side to discharge the dust therefrom after it has been separated from the cinders. The front is formed inclined or sloping, and of a piece of solid sheet metal, up which the cinders and ashes are to be swept on to the open bottom.—Patent abandoned.

1681 S. BIRCH, Belfast. *Handkerchief boxes.* Dated May 31, 1869.

This consists in uniting the two halves of handkerchief, glove, and other similar fancy boxes by means of an elastic band or bands of india-rubber fixed at each end, and so arranged as to form hinges for the box, which hinges at same time have a constant tendency to close and hold the box in the closed position.—Patent abandoned.

1682 W. R. LAKE, Southampton-buildings, Chancery-lane. *Propelling machinery.* (A communication.) Dated May 31, 1869.

This consists, principally, in combining with a rotary shaft and with a wheel or wheels located and fixed thereon a double set of spring pawl levers and pawls or clutches, each lever being hung and rocking loosely upon the shaft, and bearing a feed pawl or clutch which grasps or impinges against the periphery of the wheel as the pawl arm of the lever is moved in one direction, thereby rotating the wheel, the pawl arm being carried in the opposite direction into normal position by a suitable spring, and each lever and pawl working independently of the other, so that the shaft may be driven by one pawl alone or by both together, or both alternately, and without regard to extent of movement, there being no cranks and no dead centres to require a certain fixed play of the pawl lever.—Patent completed.

1683 H. HOLDREGE, New York. *Making gas.* (A communication.) Dated May 31, 1869.

This consists in the manufacture of heating and illuminating gases by decomposing highly heated and finely divided jets of steam by means of anthracite coal. In the combination of the decomposing retort having a channelled, grooved, or flued flooring of perforated tiles of fire-clay or other suitable material, with a steam superheater and steam dryer for the purpose of drying and superheating and distributing the steam or vapour of water.—Patent completed.

1684 J. H. JOHNSON, Lincoln's Inn-fields. *Stoves.* (A communication.) Dated May 31, 1869.

The back of the improved stove is built by preference of firebrick, and the front is composed of three movable grates of which two usually remain in a vertical plane, whilst the third is normally a horizontal plane, and joins at its front edge the lower portion of the lower one of the two vertical grates. The fuel for the main portion of the cooking is contained within these three grates, but a smaller supplementary fixed horizontal grate is also provided for use in minor operations, such as warming milk and the like, when the main fire need not be used.—Patent abandoned.

1685 F. A. CALVERT, Manchester. *Engines.* Dated June 1, 1869.

This relates to a previous patent dated October 17, 1864 (No. 2,555). According to the present invention the cylinders are open at the top and closed at the bottom by the foot valves, and are secured at each end of the cistern or tank, to which are fixed the standards supporting the journals of the flywheel shaft, at each end of which is a disc in which the crank pins are secured. Within each cylinder is a piston connected to the crank pins by the rods. Between each piston and its foot valve is the float. The pistons and floats are provided with spring and other packings of any suitable description.—Patent completed.

1686 T. R. CLARKE, W. BYWATER, T. LAWSON, and O. L. LISTER, Leeds. *Felted fabrics.* Dated June 1, 1869.

This consists, first, in the manufacture of felted fabrics by employing bats or slivers made with their fibres crosswise, or at right or other angles to the direction of the length of the batt or sliver combined with other batt or batts or slivers having fibres thereof laid in the direction of its length of such other batts or slivers.—Patent completed.

1687 A. RUSHWORTH, Nottingham. *Circular knitting machines.* Dated June 1, 1869.

The inventor employs a circular knitting machine which may be of the usual construction, but in the circle of needles he forms a space by taking away one needle and also the lead in which it is cast, and instead, inserting a piece of brass or other suitable material with a slit cut in it or a hole drilled through it vertically in such wise that the stem of a needle is free to turn in this slit or hole, such needle having its head or bearded end made of a shape and gauge corresponding with the other needles, but the stem is made somewhat longer, and is passed down the hole in the piece above named, and also into a hole drilled to receive it in the upper end of a short rod, the needle being held fast in the rod by means of a short screw, so as to enable the needle to be adjusted as required, or a new one to be inserted; this needle does not slide up and down, or horizontally, when at work, but revolves one way during one revolution of the circular head and the reverse way the next succeeding revolution.—Patent completed.

1688 C. H. GARDNER, West Harding-street, E.C. *Lubricator.* Dated June 1, 1869.

This consists in a chamber, vessel, or receiver closed on all sides, or nearly so, except at the bottom, where a small aperture is provided through which passes a rod, wire, bar, or pin, grooved, furrowed, or channelled on its external surface. This rod, wire, or pin reaches up to or into the interior of the vessel or chamber through a suitable guide block or surrounding piece in which it may be held preferably by a bent wire. The lubricating agent trickles down the furrows or channels of the rod, bar, or pin, on to the shaft journal.—Patent completed.

1689 O. BARRETT and G. P. WHEELER, Mitcheldean. *Mortar.* Dated June 1, 1869.

For 1 ton of this improved mortar the inventors grind and otherwise prepare by suitable machinery the following materials:—283lb. of lime, either caustic or hydrate, 1,728lb. of slag, *i.e.*, the vitreous mass which covers fused metal in the smelting hearths, and is known as dross slag or scoriæ, and in chemical terms by the names of silicate of lime and silicate of alumina, and 224lb. of calcined coal shale clay. Total, 2,240lb., equal 1 ton.—Patent completed.

1690 J. WARHURST, Whaley Bridge. *Preventing door draughts.* Dated June 1, 1869.

The inventor closes openings or apertures by means of a bar of wood, metal, or other suitable material arranged to work in a rebate formed in an outer casing, mould, or skirting applied to the bottoms of doors and connected to metallic plates, to which spiral springs are affixed, so that as a door thus provided closes, the end of such bar comes in contact with a projection formed in the door jamb, and is thereby pushed forwards and downwards by the action of the metallic plates, which act in the same manner as cranks, and in turning wind up the spiral springs.—Patent completed.

1691 H. BROWNING, Limehouse. *Varnish or paint.* Dated June 1, 1869.

The inventor prepares a solution which may be used either mixed with "ground colour," as a "paint," or by itself as a "varnish or preservative solution," and in either form is equally applicable to stonework, woodwork, or iron. The ingredients are a gum resin, by preference, "gum dammar," spirit and sugar of lead, to which may be added, especially for stonework, a little wax and corrosive sublimate. The spirit preferred is any one of the various rectified spirits of coal tar or petroleum, such as benzine and benzoline, now so largely manufactured.—Patent completed.

1692 J. S. STUBBS, Lincoln. *Steam engines.* Dated June 1, 1869.

The inventor dispenses with cylinder covers and bolts, slide bars, front glands, slide blocks, gudgeon column, and bolts, and he employs a cylinder of the common form, but with a partition in the centre, and with two pistons instead of one. The engine receives the steam from the centre of the cylinder instead of at each end, as in the old form, so that it has not to be conveyed by passages the length of the cylinder.—Patent abandoned.

1693 C. F. WALDO, Bread-street, Cheapside. *Sewing machines.* (A communication.) Dated June 1, 1869.

The first part of this invention relates to what is called and known as the "tension." The second relates to what is known as the "threading of the machine." The third relates to the adjustment of the needle to the shuttle race. The fourth relates to guarding the needle against breakage by the shuttle nose. The fifth relates to the raising and to the turning the presser foot. The sixth relates to what is called and known as the feed.—Patent completed.

1694 J. A. BINDLEY, Burton-on-Trent. *Attemperators* Dated June 1, 1868.

This consists in employing instead of the ordinary attemperator or pipe and casing a pair of tubes laid side by side and coiled together into a large tapered spiral roughly approximating in form to that of the cask in which they are to be employed, but of smaller diameter than the interior of the cask. The inventor connects one of these pipes with the inlet nozzle and the other with the outlet nozzle, usually employed with the ordinary attemperators, and he connects the extremities of the pipes themselves at the termination of the spiral, so that the course of the water shall be along one and back by the other throughout the entire spiral.—Patent completed.

1695 M. WRIGLEY, Oldham. *Railway accident preventor* Dated June 2, 1869.

This consists principally of a fence or railing that can be raised at the edge of the platform when required to prevent persons from crossing the line or entering or leaving the carriages, and lowered again when not required.—Patent abandoned.

1696 R. B. COOLEY, Nottingham. *Hats.* Dated June 2, 1869.

When forming a hat or other covering for the head from one thickness of elastic fabric only the inventor applies a proofing to such fabric. He next takes the pieces of fabric of suitable form and prepared as above described and steams them, after which they can be shaped or blocked into a seamless hat or other covering for the head.—Patent completed.

1697 J. FLETCHER, Ashton-under-Lyne. *Union cocks* Dated June 2, 1869.

This consists in so arranging a steam or other cock that it not only answers the ordinary purpose of a cock for opening and shutting off the supply, but it also forms a union joint which may be readily uncoupled if required.—Patent completed.

1699 A. WATT, New Cross, and T. KNOWLES, Edgbaston. *Printing surfaces.* Dated June 2, 1869.

The inventors first construct a roller by casting or drawing a flat surface, as may be required, of any suitable cheap metal or alloy, but they prefer to employ steel or iron of a tough quality with about one to two per cent. of lead mixed therewith just previous to casting. This mixture of iron and lead or steel or other suitable metal or alloy forms the body of the printing surface, or the body or base may be composed of iron or steel alone and may either be cast or drawn, and the inventors prefer to employ this surface in the slightly roughened state in which it leaves the moulds used in its production if produced by casting, or the surface may be specially roughened by any convenient means. Hitherto, when it has been attempted to deposit metals upon metallic or other surfaces by electro-deposition they have undergone a special preliminary treatment for the purpose of rendering them smooth, but it is found that this preliminary preparation is positively injurious to the purpose to be attained, namely, permanent adhesion of the deposited metal. The inventors insert or cast into the surface of the base or body of the roller or other surface thus obtained, and which surface is intended to receive the copper deposit, a number of copper screws or copper-headed screws having expanded heads, or they insert or cast into such surface, at intervals of a few inches, ribs or strips of copper, the surfaces of such screw heads or inserted ribs or strips of copper being left flush with the face of the body or base of the cylinder or other surface.—Patent completed.

1700 G. V. TURNBULL, C. SALVESEN, and R. IRVINE, Leith. *Lubricants.* Dated June 2, 1869.

The inventors take a certain proportion of heavy oil and subject it to heat in any suitable vessel, and when so heated they add to it resin or other suitable substances, such as gum, in various proportions, which are dissolved in the same. The result is an oil holding resin, gum, or other substances in solution.—Patent completed.

1701 B. J. B. MILLS, Southampton-buildings. *Alarm for boilers.* (A communication.) Dated June 2, 1869.

This apparatus is provided with a water chamber or reservoir, located externally of the boiler above the water line and communicating with the interior of the boiler through a pipe at the lowest level to which the water in the boiler can properly be allowed to descend.—Patent completed.

1702 N., G., and E. SMITH, Thrapston. *Cutting leather.* Dated June 2, 1869.

This consists, first, in so cutting the material into the lengths and widths required that the skiving is effected at the same time and by the same instrument which effects the cutting, whereby the material, which has been heretofore lost by skiving, is saved and time is considerably economised.—Patent abandoned.

1703 J. H. SMITH, East-road. *Velocipedes.* Dated June 2, 1869.

The guiding handle is made to turn on a socket fixed to the frame, and a spring is adapted to the front wheel to prevent vibration of the guiding handle and riders' arms in going over rough or uneven roads. Another improvement consists in forming the fork of the front wheel cranked, whereby the front wheel always inclines to a straight line with the back wheel.—Patent abandoned.

1704 E. BEMELMANS and A. VAN VOLXEM, Brussels. *Working railway signals.* Dated June 2, 1869.

The inventors employ a series of longitudinal bars (having notches or grooves cut in them of different forms and dimensions) and connected with the levers of the switch mechanism, and also with that of the signals. These bars are connected (and give motion by means of elbow or bell-crank levers) to a series of transverse bars, which also have cut in them notches or grooves which work into and correspond with the notches or grooves on the longitudinal bars, so that the whole system of bars and levers is connected together.—Patent abandoned.

1705 F. R. A. GLOVER, M.A., Brading, Isle of Wight. *Anchors.* Dated June 2, 1869.

The inventor fixes in the sides of the shank of the anchor, and at or near the centre of gravity of the anchor, a pair of studs or centre pins, to which he adapts a pair of tumbling arms, either of which will extend from below the shank or to outside of the palm, both inclusive. The outer ends of these arms are connected together by curved or straight bars arranged on each side of the anchor, and as the tumbling arms are arranged to turn easily on their centre pins, it will be understood that when one of the palms of the anchor enters the ground the lowermost tumbling arm will be thrust back, and will thus carry the arm under and beyond the upper palm of the anchor, and thereby prevent the cable from passing under the palm and fouling the anchor.—Patent completed.

1706 H. LARKIN, Leighton-road, W. WHITE, Thurlow-road, Hampstead. *Magnesium.* Dated June 2, 1869.

According to this invention the inventors add the hydrochloric acid in such proportion relatively to the carbonate of magnesia that in the solution obtained the acid shall be considerably in excess; they then partially dry the acid solution in thin layers in covered dishes at a temperature of about 110deg. Cent., taking care that there shall be sufficient aperture for the ready escape of the heated acid vapour. The vessels used may be of glazed earthenware or porcelain. When the acid solution is thus made as dry as can conveniently be done at such a temperature, the inventors remove the residue from the evaporating dishes and place it in plumbago or other suitable crucibles or vessels in which they rapidly fuse it at a red heat under as close cover as is practicable.—Patent completed.

1707 T. B. WORTH, Stourport. *Carpets and coach lace.* Dated June 2, 1869.

In the manufacture of terry fabrics, the terry loops are usually formed with yarns or threads of worsted or silk. The inventor now substitutes for these threads in parts of the fabric threads of gold or silver or other metal, or rather threads covered with such metals.—Patent abandoned.

1708 C. FRANCOIS, Austin Friars. *Goods waggons.* (A communication.) Dated June 2, 1869.

The body of the waggon, instead of being built of wood and secured to a wooden framing, is constructed of plain or corrugated iron or steel plates, and is preferably made of a cylindrical form or some such shape, so as to present no sharp angles. This wrought iron or steel body or shell is let down between the wheels, recesses being made in the bottom or under side to allow the axles to pass. A considerable portion of the body or shell, and, consequently, the load carrier therein, will thus be below the level of the platform of ordinary waggons, and the head stocks or buffer beams to which it is securely fastened. The closed ends of the cylindrical body or shell are by preference convex, and suitable entrance doors are provided in the sides of the body in some position convenient for obtaining access to the interior.—Patent completed.

1709 C. FRANCOIS, Austin Friars. *Moorings.* (A communication.) Dated June 2, 1869.

The inventor constructs a mooring with wings radiating out from it in such manner that it may readily penetrate the ground, and when it has penetrated to the required depth by slightly raising it the wings may expand and grip or hold by the soil that has not been disturbed.—Patent abandoned.

1710 A. L. SIMPSON, Stowmarket. *Composition for cleaning sheep.* Dated June 9, 1869.

The inventor takes bichloride of mercury or corrosive sublimate from 64 to 128 parts; creosote, carbonic acid, or phenol, 1 to 3; sugar, 96; starch, 8; gum, dextrine, gelatine, or isinglass, 32; and he melts and mixes these materials with water with a small quantity of colouring matter.—Patent abandoned.

1711 C. OSTLUND, Stockholm. *Lamps.* Dated June 3, 1869.

The peculiar feature in these lamps is the arrangement of the air or draught tube, which passes through the body of the oil chamber, thus keeping the oil cool. The wick

fits on the outside, and may be raised and lowered in any convenient and well-known manner, such as for instance by turning a small pinion pressing with its teeth into the meshes of the wick.—Patent completed.

1712 B. F. WEATHERDON, Chancery-lane. *Safety despatch box.* (A communication.) Dated June 3, 1869.

This consists in forming the boxes or bags with one or more airtight compartments (in which the various articles are placed) hermetically closed by grooved joints furnished with india-rubber and tightened by screws or otherwise, by which air is retained within the said compartments, sufficient for floating the bag with its contents till picked up or secured.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated December 14, 1869.

3608 T. Moore, Aston, near Birmingham. Certain improvements in castors for tables, sofas, pianos, and other purposes.

3609 J. Barlow and E. Pilkington, Bolton, Lancashire. Certain improvements in looms for weaving.

3610 B. B. de Morell, Chancery-lane. An improved method of raising navigable vessels or other heavy bodies above the surface of the water.

3611 W. Hepple, Low Walker, near Newcastle-on-Tyne, and M. Stainton, South Shields, Durham. Improvements in furnace bars and furnaces.

3612 W. and W. M'Gee, Paisley, Renfrewshire. Improvements in machinery for doubling and winding fibrous materials.

3613 R. Morton, Stockton-on-Tees, Durham. Improvements in refrigerators or apparatus for cooling liquids, which improvements are also applicable to distillation and surface condensation.

3614 P. Parkes, West Bromwich, Staffordshire. Improvements in machinery for cutting or shaping screw nuts and the heads of bolts, and for other like purposes.

3615 W. E. Newton, Chancery-lane. Improvements in harness for looms.

3616 W. E. Newton, Chancery-lane. Improvements in rotary engines.

3617 G. W. Honeyman, Gateshead-on-Tyne, Durham. An improved preparation for the removal and prevention of incrustation in steam boilers.

Dated December 15, 1869.

3618 W. C. Homersham, Willes-road, Kentish Town. Improvements in pipes and conduits, and in the joints thereof.

3619 N. P. Burgh, Waterloo-road, Lambeth. An improved double or single acting pump.

3620 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for making and breaking electro-magnetic circuits, chiefly designed for governing short or local circuits for operating signals on long telegraphic lines.

3621 E. Moss, Winchester House, Old Broad-street, City. Self-acting malt drying apparatus.

3622 E. Johnson, Manchester. Improvements in the arrangement and construction of granaries, and in machinery or apparatus for drying, renovating, elevating, and distributing grain.

3623 W. K. Stock, Darlington, Durham. Certain improvements in looms for weaving.

3624 J. Hamer, White Horse-yard, High Holborn. Improvements in steam engines, which are called Hamer's patent revolving and oscillating cylinder, with cup and ball joint for steam engines.

3625 J. Askew, Hampstead-road. A globular refrigerator for cooling brewers' and distillers' wort.

3626 J. Outram, Sevenoaks, Kent. Improvements in propelling vessels.

3627 J. H. Sams, Bon Accord Works, Aberdeen. Improvements in seed-sowing machines and manure distributors.

3628 E. T. Hughes, Chancery-lane. Improvements in wood moulding and panelling machines.

3629 T. Parry, Balham, Surrey, and J. M'Hardy, Edinburgh. An improved drag or brake applicable to waggons, omnibuses, carriages, and other wheeled vehicles.

3630 A. Hall, Quarmby, Huddersfield. A new or improved fabric, which is called Tartan reversible Astrachan, and in the means of producing same.

3631 G. Seymour, Lime street, City. Improvements in the construction of ships and vessels to facilitate the steering and propelling the same.

3632 J. S. Battye, Stirling, North Britain. Improvements in mechanism for spinning woollen and other yarns.

3633 J. H. Johnson, Lincoln's Inn-fields. Improvements in means or apparatus for reducing friction.

Dated December 16, 1869.

3634 J. Heap, Hampstead-road. Improvements applicable to earth closets or commodes and urinals.

3635 E. Tomlinson, Manchester. Improvements in furnaces for preventing the formation of smoke or effecting its combustion.

3636 J. W. Greenwood, Sussex-road, Upper Holloway. An improved fastening for buckles, called a screw strap holder.

3637 W. T. Henley, Leadenhall-street, City. Improvements in protecting telegraph wires and cables.

3638 S. Johnson, West Croydon. Improvements in velocipede carriages and vehicles.

3639 J. O. Butler and J. Nicholls, Leeds, and W. Heslop, Doncaster, Yorkshire. Improvements in the manufacture of wheels and pulleys.

3640 G. Wilson, Field Head, Sheffield. Improvements in railway wheels.

3641 W. Richards, Birmingham. Improvements in breech-loading firearms and cartridges.

3642 J. Outram, Sevenoaks, Kent. Improvements in steam motive-power engines.

3643 S. A. Buirat, Boulevard de Strasbourg, Paris. An improved process for producing engraved metallic plates for commercial indications.

3644 F. E. Duckham, Millwall. Improvements in hydrostatic weighing machines, applicable also for testing chains and other similar purposes.

3645 A. M. Clark, Chancery-lane. Improvements in the manufacture of superphosphate of lime.

Dated December 17, 1868.

3646 J. Ghisi, Lodi, Italy. A new and useful system of spherical ship, with circular steam engine, for the use of marine locomotion, and application of the machine to land locomotion, also of same system to other motive-power engines.

3647 A. R. Stocker, Thomas-street, Horselydown. Improvements in stoppers for infants' feeding and other bottles, and in the manufacture, construction, combination, and employment of the whole or part of the articles to be used.

3648 H. Willett, Arnold House, Brighton, Sussex. Improvements in the construction of groynes and breastworks.

3649 L. Sterne, Great Queen-street, Westminster. Improvements in buffers, also applicable to bearing and other springs.

3650 G. Weir, Glasgow. Improvements in slide valves.

3651 W. Foulds, Paisley, Renfrewshire. Improvements in feed-water heaters.

3652 W. Barrs, Manchester. Improvements in the manufacture of elastic webbing.

3653 R. Idle and G. Naylor, Earls Heaton, near Dewsbury, Yorkshire. Improvements in apparatus for consuming smoke.

3654 E. A. Inglefield, Grove End-road, St. John's Wood. Improvements in hydraulic apparatus to be used on shipboard for utilising the pressure of the external water.

3655 J. L. Hancock, Ley Hill, Sutton Coldfield, Warwickshire. Improvements in apparatus for crushing or breaking bones for domestic and other purposes.

3656 T. C. March, Ambassadors' Court, St. James' Palace. Improvements applicable to the ornamentation of articles of furniture and to the interior decoration of houses.

3657 G. Rhodes, Lincoln. Improvements in apparatus for actuating the valves of steam engines.

3658 A. M. Clark, Chancery-lane. Improvements in jacquard apparatus.

Dated December 18, 1869.

3659 W. Carver, Manchester. Improvements in sewing machines.

3660 R. C. Goddard, Stockport, Cheshire. An improved portable cooking apparatus.

3661 J. C. Martin, High-street, Barnes, Surrey. An improvement in the manufacture of finings as a substitute for isinglass for clarifying wine and beer.

3662 W. E. Gedge, Wellington-street, Strand. An improved system of pessary.

3663 W. Hargreaves, Soho Ironworks, Bolton, Lancashire. Certain improvements in steam boilers.

3664 W. Foulds, Paisley, Renfrewshire. Improvements in apparatus to promote circulation in steam boilers.

3665 J. Smiles, Birmingham. Improvements in breech-loading firearms.

3666 W. Potts, Handsworth, Staffordshire. An improved apparatus for effecting or promoting the ventilation of rooms or buildings and for preventing down-draught in chimneys.

3667 R. Nevill, Wern Ironworks, Llanelly, Carmarthenshire. Improvements in the manufacture of retorts and annealing pots and stands.

3668 J. C. Ramsden, Bradford, Yorkshire. Improvements in looms for weaving.

3669 J. M. Shiels, Preston Pans, Haddingtonshire. Improvements in preparing malt or grain for brewing or distilling, and in the means or apparatus employed there for.

3670 S. Butler, Nottingham. Improvements in the manufacture of lace in twist lace machines.

3671 S. Giles, Borough. Improvements in apparatus to be used in the fermentation of worts and other fermentable liquids.

3672 D. W. Bailey, Chelsea, Suffolk, Massachusetts, U.S.A. A new and useful process of laying composite pavements for streets, &c.

3673 H. Kinsey, Robin Hood Works, Nottingham. Improvements in the manufacture of surface condensers, hot-water apparatus, and in steam boilers and water heaters for the same.

3674 L. Woodward, Arkwright-street, Nottingham. Improvements in knitting frames.

3675 G. T. Bousfield, Loughborough Park, Brixton Improvements in the treatment of aromatic secondary monamines for obtaining colouring matter.

3676 W. L. Wise, Chandos Chambers, Adelphi, Westminster. An improved instrument for levelling and for measuring angles.

Dated December 20, 1869.

3677 J. Robertson, Glasgow. Improvements in machinery for treating and shaping metals.

3678 G. and G. A. Ermen, Manchester, and W. Foster, Pendlebury. Improvements in the construction of brushes for polishing yarns or threads, and for other purposes.

3679 M. Henry, Fleet Chambers, Fleet-street, City. Improvements in the mode of, and apparatus for, typographical composing and printing.

3680 F. Ellershausen, Ellershause, Novia Scotia, and T. Wehle, Southampton-buildings, Chancery-lane. Improvements in the means and apparatus for utilising the force of the waves.

3681 G. Newsum, Hunslet, Leeds. Improvements in means or apparatus for pumping.

3682 G. T. Livesey, South Metropolitan Gas Works, Old Kent-road. Improvements in apparatus used in the manufacture of gas.

3683 W. Morris, South Hackney. Improvements in permanent way.

3684 E. T. Hughes, Chancery-lane. Improved garments to be worn next the skin for sanitary purposes.

3685 J. Wild, Rochdale, Lancashire, and J. Smith, Halifax. Improvements in the manufacture of pile fabrics.

3686 J. H. Richardson, Poultry, City. Improvements in boxes or cases for packing and carrying eggs.

3687 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in ploughs and cultivators for tilling the soil.

3688 T. Shakespear and G. Illston, Birmingham. Improvements in sewing machines.

3689 A. M. Silber, Wood-street, Cheapside, City, and F. White, Camberwell. Improvements in apparatus for indicating time, partly applicable to revolving apparatus for other purposes.

3690 W. Galloway, Francis-street. Improvements in joints or couplings for pipes, rods, and other like articles, which improvements are also applicable for stopping pipes, bottles, casks, and similar receptacles.

3691 G. C. Fraser, Bromley-by-Bow. Improved means of disinfecting or drying clothes, bedding, or other articles, also apparatus in connection therewith.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," December 21, 1869.

2344 J. U. Fairbairn
2353 T. Leach

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.
